David et al,

I agree with you guys about audio and ALC.

I'm not going to defend those who operate 'with the knobs all the way to the right'. However, you might want to remember that some of these guys may be compensating for what you might consider to be poor antenna installations with raw RF power or over-amplified/over-processed audio, especially if they live in CCR-restricted neighborhoods where they can't put up the antenna system they might otherwise.

Or, they just might want to splatter all over the bands and bust any pile-up no matter what, because they can.

I can't run the antenna system I'd like -- not because of CCR restrictions, but XYL restrictions -- so I do the best I can. It's not a bad discussion to have, especially considering that many newer amateur operators are 'discovering' the quality and capability of these older rigs while bringing with them some of the pre- or misconceptions from other services (as mentioned in a previous post).

Audio processing has been around for quite a while (remember the Vibratrol CA-300? I still have one, actually), and, when used properly it's a good thing. When. Used. Properly.

Anyhow, not trying to hijack the thread, just observing some possibilities. It's up to us as amateurs to educate our fellow amateurs on topics like this, in my humble opinion, and this is a good venue in which to do it.

Tony KA5TRO

Subject: Re: [TS-520_820_530_830] Re: how to adjust alc

Have you noticed how signals sound on the bands nowdays? Too much audio, too much back ground noise. It seems as though you are suppose to run the audio wide open, the speech processer on way too high and the rit turned just a little bit. The manual explains all this, but I guess they get lost when the rig is unpacked.

Thanks for that info
i will like most of the posts copy and paste it into my 830 files
yes i think 1980 would be very close
when did production end with the ts830s
thanks again for your time

> Don, in the Database section of the group there is a folder giving dates for serial numbers which were submitted by original owners of these rigs. The TS-830 data that is there (it's sparse) is below and from this table you can see that the 1111111 number on your radio most likely is from 1980 or 1981. Keep in mind that the distribution chain from parts production to finished goods to distribution to retail outlet to customer could be well over a year, so the radio you have may have been built in 1980 and sold in 1981 or even 1982. Just bounding it to 1980-1981 may be about the best you'll really do.

> > >
> > > Sorry, Don. I can't date based on the serial number. I am sure if you look hard enough at the tops of the ICs you will find some with 4 digit date codes. There are usually a couple of rows of numbers, the top is usually the part number and then under that will be either a lot code or date code and then under that will be the date code or lot code. Sometimes there is no indication of the lot code, just the 4 digit date code. There is no hard and fast rule about the placement of the date or lot codes but usually they will be under the part number type. Look for codes that start with 8. I am guessing that the radio was produced in the 80s era, I don't remember the range of years. Just a guess on my part. Incidentally, if you see a 3 digit date code then the assumption is that the omitted digit is the year (probably 8) and then the first number is the year then two digits for week. In my prior example, the code would be 327 where 8 is implied and the year would then be 83.

Check several different types of parts and see if most are within a few weeks range. It is
a good bet that the date of your Kenwood is about 3 months younger than the latest date
codes you can find on the ICs. I am not certain if Kenwood stamped test or acceptance date
codes on assemblies, but if they did that is a better approach or at least a great cross
check.

Mike,
That was a great very cohesive explanation. I am not too bright and I understood it. I have gotten so much conflicting advice about tuning the exciter (830S) and the amp that I have been left confused more than usual. This sounds like good technically backed advice. Thanks

I heard this over a local FM repeater;
"On a sideband radio you can turn the RI.T . to the right to get more power in your upper sideband and to the left to get more into the lower sideband." The speaker sounded sincere about this technical revelation.

As Ger, PE1CZG indicated....I had the same ALC issue with my TS-830s. As detailed on the www.k4eaa.com site..... the RL-1 relay was replaced. Problem fixed.
Ken details how to test the relay on his web page also.

Best to you
73
Mike

> You need to examine relay RL-1. I replaced the relay with I ordered from K4EAA. See here his story about RL-1: http://www.k4eaa.com/RL-1.htm

> >
> > If you are tuning the 830 up in CW mode and while watching you external watt meter, do you see any intermittent or instability in the RF output? If not then it's quite possible

the source of your problem is not the AF unit relay.
> >
> > Since you are not the original owner it's quite possible a previous owner may have experienced a similar problem and was instructed to replace R15 and R16 on the Rectifier Unit. If the previous owner's soldering skills were poor, there may be an intermittent poor solder connection to one or both resistors which is contributing to your intermittent problem. Therefore, I would check the solder connection to R15 and/or R16 before moving on to relay RL1 on the AF Unit board.

It would interesting to hear his explanation how "RIT" controls the transmit frequency especially since "RIT" stands for "Receiver Incremental Tuning" and has nothing to do with the transmit frequency.

In addition to my last response, "RIT" is disabled in transmit. The next time he talks about this, ask him to explain, in detail, how RIT affects the transmit frequency. I would be interested in hearing his explanation.

If you turned the RIT either fully right or left , all you would do is shift the tuned FREQ , and so not be able to understand the tramsmitting station,

It would not affect the output power of the transmitter .

Cheers,

Jeff

Theres all kinds of theories out there isn't there? Maybe we ought to write a second Handbook just for grins. I can understand mistakes when someone just doesn't know, but I have heard some misunderstood ideas that almost turned into preaching on the air. I just move off frequency when these come up.

The RIT pot varies a DC voltage that is applied to a varicap diode in the VFO. As the RIT control is rotated which varies the DC voltage, the varicap diode capacitance value changes resulting in a change in the VFO frequency. There are a few other "fixed value" components in addition to the varicap diode. These components contribute to the changing of the VFO frequency when RIT is enabled.

When switching to transmit, a relay terminal "disables" the RIT control, allowing the VFO to return to its original frequency. Switching back to receive, the relay terminal enables the RIT circuit etc.

Ah Mike, he was probably referring to that little known, undocumented,
and secret tweak by activating the XIT button and then turning the
RIT/XIT control. Several active CB'ers told me about this revelation back
in the early 80's. They only spoke the truth and they believed they had
extremely high technical skills to come forth with this information.

Hello,

Just want to do a quick post since I just joined this group today after buying a TS-830S this morning. See her run at the sellers shack, but I have to wait til I get a suitable meter/tuner/dummyload before I can use it. (I'm current am using a TS-50S that's on loan to me)

So I'll try not to post too many dumb questions.. I said *try*...
I've been licensed just over a year now, and looking forward to getting on the air with my new used TS-830S. It just has one smallish problem, a broken power switch that's luckily in the ON position, bit I'll replace that in time.

Hi Joe,

The "S" model of the TS-820 includes the digital display. You didn't say whether the digital display is working or not, or even if it's present in your 820S.

The sole purpose for the 5V-AVR board is to provide a regulated 5VDC to the digital display Counter Assembly Unit.

If the Counter Assembly Unit has been removed, for what ever reason, then there is no need for the plug to be inserted onto the 5V-AVR Unit. it's possible the plug is laying on the chassis if the Counter Assembly has been removed or if the 7805 regulator is damaged (failed). There are 3 pins on the plug, one is the 14VDC input source voltage, one is the regulated 5VDC output, and the other is ground.

Topic: 30755 Message: 30800

Hi Joe,

Connect the 830 to a dummy load, if you have one. Tune the 830 up to full output in CW then switch to sideband, either USB or LSB it doesn't matter, and set the meter switch to ALC.

Set the MIC gain to 11 o'clock, press the PTT button on the microphone, then speak into the microphone. Do you see any indication on the meter? If there is an indication on the meter, most likely mid to upper ALC scale or higher, then I doubt the AF Unit relay is the source of your problem.

This MIC gain setting should not be considered to be the normal setting. You will notice I said to set the MIC gain at 11 o'clock. This is to ensure the transmit audio will ensure ALC is produced during this simple test ONLY.

Are sure you need a "TS-801" or a "TS-820"? I've never heard of a TS-801.

If you need a manual for a TS-820 then you can download it from Gordon's website

www.n6wk.com/kenwood/

Excellent. Thank you! Will check.

Sorry for the delay. Been busy.

VY 73,

Paul

30806. Re: [TS-520_820_530_830] Question About "IF Shift" Control

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-12 17:10:54 UTC
From: Jim S
Topic: 30804 Message: 30806

The IF Shift control, moves the center frequency of the receiver's Intermediate Frequency Amplifier's passband. As you move the control away from the center position, you will notice that first the high frequencies disappear, leaving only the lower ones, and then as you move it in the other direction, the lows will disappear, leaving only the high tones or frequencies.

The control's most useful function is to eliminate interference that is either above or below the desired range of frequencies. For instance, if a carrier is making a lot of racket at 2.5Khz, you can turn the IF shift down so that frequencies only below 2.5Khz will come through. This will make an SSB signal sound a bit "muddy", but at least you will be able to copy the other station.

Another name for the IF shift is Variable Passband Tuning , but this is usually a more refined control, in which both the lows, highs and center frequency can be altered to suit the situation. IF shift generally moves the center frequency from one side to the other, and the passband only actually changes as the shift reaches the extremes of its influence. BTW, the IF shift does NOT change the actual center frequency. A 1000 Hz tone will remain a 1000 Hz tone, as long as it is within the passband, no matter how much above or below that tone is removed.

Hope this helps ! 73, Jim AG3Y

Subject: [TS-520_820_530_830] Question About "IF Shift" Control

Can anyone tell me what the IF Shift control on my 530S does? This is the first radio that I have owned with this control.

The PLL Unit's VCO frequency will change when you adjust the VFO but once you arrive at your operating frequency and stop adjusting the VFO, switching between receive and transmit the PLL Unit's VCO frequency should be stable, not change.

I assume the display is off the same amount on ALL bands.

Check the 830 service manual alignment section, step 8, and adjust as necessary to ensure the counter's reference oscillator is at 1Mhz.

Topic: 30804 Message: 30809

A useful control, especially if you have another station close by.

You can then shift the IF to move its passband away from the interfering station. The wanted signal will be affected, but the interfering station much more so.

Incidentlly, I didn't realise the 530 had this control - my lowly 520 doesn't, which is a bit of a pity.

Joe and all,

To be precise: my TS-530SP S-meter and ALC readings where intermittent interrupted: when I listen to a station with S9 or whatever reading, the S-meter drops to nil. In that situation I had no ALC reading as well. IP,RF and HV readings where still there.
Don't know what the relation was but exchanging RL-1 did the trick.

The guy who made that statement about RIT probably had a VHF FM rig that only had a channel selector and volume control, maybe a squelch knob that he kept turned fully clockweise to make his signal louder ! :D

From: w5rkl <w5rkl@yahoo.com>
To: TS-520_820_530_830@yahoogroups.com
Sent: Mon, April 11, 2011 7:33:15 PM
Subject: [TS-520_820_530_830] Re: how to adjust alc

The RIT pot varies a DC voltage that is applied to a varicap diode in the VFO. As the RIT control is rotated which varies the DC voltage, the varicap diode capacitance value changes resulting in a change in the VFO frequency. There are a few other "fixed value" components in addition to the varicap diode. These components contribute to the changing of the VFO frequency when RIT is enabled.

When switching to transmit, a relay terminal "disables" the RIT control, allowing the VFO to return to its original frequency. Switching back to receive, the relay terminal enables the RIT circuit etc.

Hello Ger,

The new information about the S meter being intermittent changes things. I wasn't aware the S meter would fail, unless I missed it in a previous post/response. I only knew of the intermittent ALC. You said the meter switch positions IP, RF, and HV, in transmit, all worked as they should which didn't indicate a relay issue. You also said the 830 produced full stable RF output in CW mode. That's why I asked you to tune up the 830 for full output then switch to sideband and speaking into the microphone to see if the meter would display any ALC with the meter switch set to ALC.

A recommendation if any future problems occur, try to include as much information as possible, even if you don't think it is important.

Congratulations on fixing your 830.

Hello Mike, Ger, and ALL-

I think Mike (W5RKL) may have my original post with my question about an intermittent ALC indication on my TS-830S confused with Ger's post in response to mine. My S Meter, IP, COMP, and HV settings are working just fine. I believe it was Ger who mentioned that he had an intermittent meter that was fixed by a replacement of RL-1. No biggie, just wanted to clear the record.

Mike, I've followed your suggestions about tuning the rig up and speaking into the mic with the mic gain set at 11 o'clock. I have no ALC reading at all.

Today, I did the K4EAA recommended "tap test" on RL-1. At first I noticed no change in the meter. I tapped a couple more times and then, viola! ALC is back. It's been working fine all day. This leads me to believe the relay contacts weren't making sound contact or it was a sheer coincidence. Either way, I may end up just replacing the RL-1 as a precautionary measure.

Thanks for your assistance!

73 with regards,

Joe WS8X

It does appear I got you and Ger mixed up. Sorry about that.

As I said if you saw ALC during the simple test then the relay probably wasn't the source of your problem. However, as you found out by tapping on the relay it does appear the relay could possibly be the source of your problem.

You might also clean AF Unit plugs 7 and 10. Plug 7 is where the meter connects and plug 10 is where the ALC flows from. There are other circuits that flow through these plug but those 2 plugs, if dirty or making intermittent connections, can result in the same symptoms. Just another thought.

My S Meter, IP, COMP, and HV settings are working just fine. I believe it was Ger who mentioned that he had an intermittent meter that was fixed by a replacement of RL-1. No biggie, just wanted to clear the record.
>
> Mike, I've followed your suggestions about tuning the rig up and speaking into the mic with the mic gain set at 11 o'clock. I have no ALC reading at all.
>
> Today, I did the K4EAA recommended "tap test" on RL-1. At first I noticed no change in the meter. I tapped a couple more times and then, viola! ALC is back. It's been working fine all day. This leads me to believe the relay contacts weren't making sound contact or it was a sheer coincidence. Either way, I may end up just replacing the RL-1 as a precautionary measure.

worked as they should which didn't indicate a relay issue. You also said the 830 produced full stable RF output in CW mode. That's why I asked you to tune up the 830 for full output then switch to sideband and speaking into the microphone to see if the meter would display any ALC with the meter switch set to ALC.

Theres all kinds of theories out there isn't there? Maybe we ought to write a second Handbook just for grins. I can understand mistakes when someone just doesn't know, but I have heard some misunderstood ideas that almost turned into preaching on the air. I just move off frequency when these come up.

Thanks Mike, It does have the digital display and works good except it fluctuates on ten meters. I guess it is pulling the 5VDC from some where else.

Joe,

The Relay Unit has a zener diode, D1 (BZ-052), and a 220 ohm 2 watt resistor that produces 5VDC from the 14VDC supply. This 5VDC supply is applied to the PLL Unit from Relay Unit plug RL1 pin 13.

I don't believe the Relay Unit 5VDC supply is designed to power circuits in both the PLL unit and the Counter Unit at the same time.

I am selling my Kenwood TS-520 (complete with a replica of MC35 microphone) plus a MFJ-816 SWR-wattmeter for 150$. I am selling it because I am relocating abroad.
The rig has an issue that I previously described in this post:
http://groups.yahoo.com/group/TS-520_820_530_830/message/26792
However the problem seems to be just related to the reading, since the rig outputs what it is supposed to. I use it on weekly bases it on 10, 15 and 20 meters receiving consistently good reports and easily making DX contacts just using a simple dipole. Rarely used 40 meters. Never tested it in transmission on 80 meters. I do not ship it, so if interested you have to come and pick it up (I live in Tucson, AZ). You are more than welcome to test the rig. If interested contact me at azuccolo@...

Thanks

Andrea

Good morning everyone,

Can anyone give me a source for American made microphone connectors and panel jacks? These ubiquitous Chinese connectors are worse than useless; they do not provide good low resistance contact nor do they provide for positive orientation (e.g. a 4 pin microphone jack can be inserted 4 different ways.)

I require 4 pin and 6 pin panel jacks and connectors (plugs.)

73,

Russell

Hi Joe,

Now that's strange. The only reason I can think of to do that is if the plug failed. Those plugs do fail now and then, the plug's female metal socket that plugs into the board's pin, sometimes fail or the wire to the plug's female connector may have broken.

You might check the display's alignment steps in the service manual. I can't remember then right off the top of my head so check the service manual for details.

30832. Another filter question

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-15 21:47:55 UTC
From: KA5TRO
Topic: 30832 Message: 30832

So I now have both a TS-530SP and an -830S and am trying to figure out the filter 'options' between the two.

I have installed all three filters into my 530SP - the stock S, a C, and and SN. I have the jumpers set for A == CW and B == SSN, as I do more SSB phone than I do CW. My understanding is that the only thing I'm giving up with that is a wider CW filter bandwidth than I get with this setup (I give up 2.4kHz for 1.8kHz but still get 500Hz with NAR SW on).

However, now that I'm looking at setting up the filters in the 830S, I'm confused by the options. My 830S has the YK-88S1 filter installed in it (which I assume was standard) and no other (well, there is the Murata 455K filter in it, but I assume that's not germaine to this discussion). So, apparently, if I'm unerstanding this correctly, the 830 will support either the YK-88C/N or the YK-455C/N *but not both*.

So I'm left to assume that the filtering in the 830 is set up considerably differently than the 530, and that there is no option for wide/narrow SSB filtering -- that all is done with IF Shift and Notch, then? Or am I missing something?

Thanks and 73

Tony KA5TRO

30833. TS-830S Bias Adjustment

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-15 22:40:50 UTC
From: Charles Coffee
Topic: 30833 Message: 30833

Have a TS-830S on the bench. Initially found R15 (open) and R16 high - replaced both
with 5% 56K resistors.

However, I can not seem to get the bias adjustment set to 60ma now.
SG SW = On, Mode = USB, Meter = IP, Heater ON, FIX = ON,
Drive Control = Fully Clockwise.

No matter how I turn the Bias control pot on the rear, I can not get any reading on the meter.

Any Idea on what I am missing here ? The above is from pg 33 of the service manual, unless I have missed something.
Rig is connected through watt meter to a dummy load, no mike, no key.

Before I screwed with the bias pot, I had over 100 watts output on 40 Mtrs.

Thanks

Chuck, KJ4GU

Hi Charles,

More than likely your problem is the relay on the AF Unit.

The AF unit relay controls the bias level when switching from receive to transmit.

If you have a DC volt meter, connect the Red lead to the AF Unit's "FG" terminal and the Black lead to chassis ground. Set the DC meter to measure at least 200VDC. The DC meter should show a high negative voltage around -96 to -110VDC. Key the transmitter with either the MIC PTT button or the SEND switch. Look at the DC meter. If the voltage remains the same as it did in receive, the relay on the AF Unit is most likely the source of your problem.

Ken, K4EAA, sells a direct replacement.

Charles,

I would check the new resistors you just wired with a good ohmmeter, just to be sure you didn't misread their values, it's quite easy with modern multi-colored resistors.

Just to be sure, I would also check th PA HV with the front panel meter, should be around 900 volts, the screen grid voltage, shoud be around 200-230 volts, and the grid voltage, should be around -130 volts in receive and -60 volts in transmit mode, key down. Check what you expect to find with the schematic or the service manual, just to be sure of my memories...

Tony:

I put a new SSB filter in my TS-820S last year and I explored the options then. Suggest you go over to the International radio (INRAD) website and look at what they have in the way of wide and narrow filters available for your 830S.

P.S. DO NOT BUY A USED FILTER! People who say that if they are Okay externally then they will work fine do not know what they are talking about. I have two stock Kenwood SSB filters I tried in my 820S. One only does USB and the other only does LSB; they both look fine externally but are defective.

Good Luck!

Topic: 30837 Message: 30837

I picked up a VFO520S to replace the VFO 520 I was using with my 520s.
There is a loud AC like hum coming out of the speaker. It does not matter what I set the switch at; the hum stays the same. It is quite loud. I know it is not the cable because the VFO520 works as it should?

Any suggestions? How much would K4eaa charge me (if he even works on them?)

By the way it sure looks good

k4ynd,

Is rig new to you? If so....a good cleaning of all connectors/connections may be in order..if you have had the rig for sometime...clean the connectors/connections anyway. Does the meter seem to function OK when other functions are used...ALC, Ip, HV? Clean the meter switch too. When using the "CAL" signal...does your meter move up scale?
You can get "in the park" by: removing any antenna connected to the ANT connector on the back...locate VR2 & VR3(round white plastic things) on the IF BOARD...they are back by the 4 capacitors on the back end of the board. With the RF GAIN fully up (full clockwise) adjust VR2 for "ZERO." Dial up 14.175Mhz or so...turn "CAL" signal on....turn VFO knob and DRIVE control to get maximum reading...adjust VR3 for an S9 or maybe a bit more. Not perfect but it will get you close enough.

wn9vmr,

when you say "not stable" what do you mean? Are you using a digital display(DG-5) or some other such device? Is it intermittent, drifts, or ??? These rigs have been around for a good number of years...and even though the VFO is mostly sealed...gunk can and does get in. Get yourself some good cleaner/lube....DEOXIT works well. Make sure rig is off & unplugged. Remove top cover...be careful of the speaker wire! The VFO is the "silver thing".....can't miss it. Put rig on its left side..there is a small panel, attached with two screws on the now " top" of the VFO. It's a pain..but you have to remove 1 screw (I usually do the rear one) and loosen the other..pivot it out of the way. Look at the inside back of the VFO with a BRIGHT light... you may have to turn the main VFO knob to get the plates out of the way....you will see a bowed piece of spring metal...it's a "wiper." Spray cleaner (sparingly) on this connection... operate VFO to the ends of its travel...both ways..several times..then spray cleaner.. do it again..you can also use some "canned air" to blow off the area after the cleaner is used. Check for operation..... if it doesn't work...it's a good place to to start...and can't hurt!..............good luck.

30842. Stubborn TS-820 voltage problems

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-16 06:36:56 UTC
From: ae5uu
Topic: 30842 Message: 30842

Good morning all,

I have been fighting a stubborn voltage problem for some time. I would appreciate some help.

First a new distraction with symptoms:

60ma idle is correct.

In TUN, no PLATE current registering on IP meter setting.

In CW, no current showing with adjustment of LOAD and PLATE controls

No transmit (NONE OF THESE SYMPTOMS WERE AN ISSUE UNTIL TODAY WHEN I REPLACED FINAL UNIT R-2, R-3, R-5, R-6. I ALSO REPLACED L-1 AS PER KIT VALUE (6.8UF, 500MA) SUPPLIED AS KIT FR-100 BY K4EAA, BUT NOW NOTICE THE THE VALUE FOR L-1 LISTED IN MY PARTS LIST IS 470UF, SO I WILL SWAP BACK L-1 AND HOPE FOR THE BEST)

ALL THE ABOVE IS NOT MY MAIN PROBLEM. MY MAIN PROBLEM IS DETAILED BELOW:

Meter does not increase reading when RF GAIN is rotated CCW (although the receive audio is reduced gradually as it should be.)

In TUN, no ALC reading with DRIVE control on ALC meter setting.

-6vdc bus reads +0.59vdc

+3.3vdc bus reads 3.3vdc with IF UNIT IF3 unplugged, +6.4vdc when IF Unit IF3 is plugged in.

No S Meter reading.

BELOW IS A LISTING FROM ALL MY VOLTAGE TEST POINTS. ALL APPEAR CORRECT WITH THE POSSIBLE EXCEPTION OF THE RECTIFIER UNIT "SG" AND "STB" AND THE HV UNIT "HV" TERMINAL (I DON'T KNOW WHAT THE VALUES SHOULD BE.)

+14vdc

AF-AVR board AF1 pin 3
IF Board IF1 pin 3
Fix-Vox Board FX3 pin 3
Relay Board RL1 pins 7-12
RF Board RF1 5
Rectifier Board Terminal "14"
ALL POINTS YIELD PROPER VOLTAGE

+9vdc

IF Unit IF1 pin 5
CAR Unit CJ2 (Mode switch set to TUN, CW, LSB, FSK,and SSB)
PLL Unit PLL2 pin 3
FIX VOX Unit FX3 pin 1
Relay Unit RL1 pins 1, 2, and 3
Relay Unit RL2 pins 10 & 14 (note: pin 14 has no wired connection)
RF Unit RF2 pin 1
VFO 2 pin plug Large pin
ALL POINTS YIELD PROPER VOLTAGE

+5vdc

Relay Unit RL1 pin 13
PLL Unit PLL2 pin 1
ALL POINTS YIELD PROPER VOLTAGE

+3.3vdc

AF-AVR Board AF2 pin 6
IF Board IF3 pin 8 (RFI)
RF Board RF3 pin 4 (RFI)
RF GAIN control Opposite end from R-2
ALL POINTS YIELD +6.4VDC WITH IF UNIT PLUGGED IN, 3.5VDC WITH IF UNIT UNPLUGGED

-6vdc

RF Board RF2 pin 2
IF Board IF3 pin 4, 5
Fix-Vox Board FX3 pin 14
ALL POINTS YIELD +0.59VDC

High Voltage

RF Unit RF2 -110vdc pin 7 (-C)

Rectifier Unit 800 Terminal +952vdc Receive, slightly less Transmit

300A Terminal +344vdc

300B Terminal +344vdc

210A Terminal +260vdc

210B Terminal +263vdc

-C Terminal -110vdc

SG Terminal -116vdc

STB Terminal +112vdc

14 Terminal +15.25VDC

HV Unit FSB Terminal +260vdc

210 Terminal +260vdc

800 Terminal +952vdc

HV Terminal +43vdc

Final Unit PD2 Terminal +260vdc

FG Terminal -100vdc Receive (spec.)
-100vdc (actual)
-55vdc Transmit (spec.)
-54vdc (actual)

SG Terminal +255vdc Receive (spec.)
+260vdc (actual
+210vdc Transmit (spec.)
+225vdc (actual)

The following parts have been replaced, in addition to all electrolytic capacitors on all boards:

1) AF-AVR Unit VR-1, VR-4, D-5, Q-4, Q-5, and Q-6
2) IF Unit Q-15, Q-16
3) IF Unit D-18, D-19, D-20, and D-21
4) IF Unit C-70, C-72, and C-142
5) IF Unit R-66, R-145, and R-146
6) PD Unit C-14, C-15
7) FIX-VOX Unit Q-13
8) HV capacitors C-21, C-22, R-6, R-7, and 2 each 0.01uf (C-14 through C-17 type)

Notes: AF-AVR Unit R-9 and R-26 not installed (jumpered by factory)
C-29 installed according to schematic (polarity is marked wrong on board)

FIX-VOX Unit C-32 replaced with 3.3uf, 50wv factory spec., was 1.0uf in my radio

IF Unit C-43 as built is electrolytic, not as listed in parts list

C-75 as built is 1.0uf, 50wv, not .01uf as listed in parts list

Firstly, I need to correct my +3.3vdc and -6.0vdc problem. Then I intend to look at Q-5 on the RF Unit. Measured at RF3, pin 6,the reading is 5.2vdc in Receive. In Transmit it changes with application of the DRIVE control. It does not change with application of the CAR control.

I know that this is a complex posting; your assistance would sure be appreciated before I pull the rest of my hair out.

73,

Russell
AE5UU

30843. "Normal" Mic Gain

Topic: 30843 Message: 30843

Just got a nice TS-830s. All my hybrid experience has been with a TS-530SP. I use an MC-60 mike. On the TS-530 I set mic gain to around 10:30 and speak about 2 inches from mike to just see occaisional ALC indication (blip). With the TS-830 using same mike I have to set the mike gain to around 1:00 and "eat" the mike to get same occaisional "blip" on ALC meter position. I have monitored with headphones and the audio sounds good. Peak reading wattmeter indicates good RF output. Having to "eat" the mike probably helps eliminate background noise from the shack, but it is very different from how my TS-530SP operates.

Anyone running same TS-830/MC-60 combination? What do you consider "normal" mic gain setting? Should I start taking voltage readings around Q19?

Thanks
Terry K9TW

Daniel,
Thanks for the reply, I always check resistors before I install them in a
circuit to make
sure they are the correct resistance and within tolerance. Burned too many
times
in the past. HV on the meter was around 850V, and a bit higher on the DMM
when reading off the HV to the finals. Still have to check the other
voltages
and check the AF Relay as Mike suggested (also Thank you Mike for the tip).

Hello Terry,

You didn't say whether you are using any transmit audio processing with both transceivers (Processor switch turned ON). You also didn't say whether the MC-60's internal amplifier is turned ON or OFF.

Since both transceivers have the same 500 to 50K ohm microphone impedance, it doesn't really matter what impedance setting the MC-60 is set at.

The TS-530 transmit audio processing is an "ON/OFF" setting, no front panel processing level adjustment other than the MIC Gain. The TS-830 on the other hand, has a separate audio processing adjustment, upper left corner above the meter, to vary the level of audio processing. Therefore, the 830's audio processing adjustment should be set with the MC-60's internal amplifier turned OFF.

If the MC-60 internal amplifier is turned ON and both transceivers have transmit audio processing turned ON, that's not a good combination. Use either one or the other, not both.

Have you opened up the VFO-520S and looked for a broken ground on the 9 pin socket and/or else where? The differences between the VFO-520 and VFO-520S is cosmetic. The internal VFO and support circuits are the same.

If you don't have the VFO-520 manual you can download it at Gordon's website, www.n6wk.com/kenwood/

Hi Mike--I intentionally did not mention the "processor" settings. What I described is with the processors off on both 530 and 830. My MC-60 has no internal pre-amp. I believe the MC-60A mic has an internal pre-amp? I have used both processors on both rigs and they both work well. I set the 830 processor pot to around 1200 to get around 6db on the "compression" scale of the meter. I have monitored and it clearly adds punch, but would be easy to overdrive.

I just wanted to find out where 830 owners using an MC-60 mic typically set their mic gain at without any processing. As I mentioned at 1:00 (6) setting on mic gain pot I have to "eat" mike to get ALC meter to begin (blip) up. This is much higher setting than is required on my 530SP. This may be normal? I will take a closer look at the two mike pre-amp circuits to see if there is a design reason for this. I see that the processors are very different with the 830 using RF clipping.

Mike --appreciate your questions and quick response. It is not a big problem. I just want to make sure rig is operating as it should as I have no operational experience with 830s. Someone told me I should be using a MC-50 mike with the 830. Doesnt sound right to me. Maybe I will inject 1000hz audio from audio generator into mike jack and run some comparisons?

TNX--Terry

Subject: [TS-520_820_530_830] Re: "Normal" Mic Gain

Hello Terry,

You didn't say whether you are using any transmit audio processing with both transceivers (Processor switch turned ON). You also didn't say whether the MC-60's internal amplifier is turned ON or OFF.

Since both transceivers have the same 500 to 50K ohm microphone impedance, it doesn't really matter what impedance setting the MC-60 is set at.

The TS-530 transmit audio processing is an "ON/OFF" setting, no front panel processing level adjustment other than the MIC Gain. The TS-830 on the other hand, has a separate audio processing adjustment, upper left corner above the meter, to vary the level of audio processing. Therefore, the 830's audio processing adjustment should be set with the MC-60's internal amplifier turned OFF.

If the MC-60 internal amplifier is turned ON and both transceivers have transmit audio processing turned ON, that's not a good combination. Use either one or the

other, not both.

Does the frequency jump suddely by 500 khz or so when you are tuning the radio? I had that problem on my TS-820S. It means that the tuning cap is shorting out due to dirt, spiderwebs, corrosion, etc.

The fix is simple although not that easy. You take the VFO out, open it up, and spray the tuning cap with an electrical contact cleaner, such as CRC Lectra-Motive. Clean up any corrosion you see at the pivot points with Deoxit, and then lubricate the pivot points with LPS-1.

Now, there is also a tantalum capacitor problem in the VCO/PD module of the TS-820 that can cause some instability as well but I don't know if a similar problem with the 520SE.

Good luck!

Randy,

I have been using an old brass straight key for years on the 520/530/830 series of radios. You can use shielded cable if you want. 1/4" MONO plug, with one wire to the "tip" and the other to the "sleeve" should be satisfactory.

Hello,
I have a TS 520S that works with good output, The processor works fine, but when I switch to alc, it is intermittent in output. It works sometimes, and then as you talk, it slowly drops in output. Sometimes you have to get real close to the mic to get any output at all, yet when I switch it to RF, there is plenty of power out. Also the S meter will not zero even when you set VR1, can't set it on zero with the antenna disconnected. I am using a dummy load for adjusting the radio. can anyone help with troubleshooting this problem?
Thanks for reading this post, Hope to hear from someone, 73.

Hi again Bruce, it just dawned on me that I had also communicated with Mike W5RKL on the Yahoo board about the Kenwood some time ago,and after watching his continued answers to other peoples questions about a consortium of different problems he might also be a real help with the display problem, at least you guys can communicate one tech to the other and understand each other. Here is an old email that he had answered to me on the yahoo groups. He seems really helpful when people talk with him. Maybe he could add something. Good Luck and thanks again Bruce, sorry for this problem, Ha you wont ever want to see a Kenwood again, ;-)) Blake N7BLZ

Wow, thanks for such a detailed explanation Mike, you can't know just how much it is appreciated. I was truly hoping that this problem was not a major mechanical issue as much as an adjustment issue. (although I am not afraid to tackle either) I am burring my head into the service manual and will study it extensively before trying to do any adjustments. Thanks for pointing me into what appears to be the right direction. I guess I just never had any idea that someone would ever change something to receive the CB" bands, at least not on one of these beautiful pcs. of history. LOL oh well, I learn something new everyday of my life. I guess that what makes living so great. Thanks again Mike, Blake KF7HHC

Subject: [TS-520_820_530_830] Re: TS-820 with Digital display, 10 meter display fluctuating and wont stop.

Hello Joe and Blake,

If the PLL Unit become unlocked, for what ever reason, the digital display will be dark, nothing displayed, and both transmit and receive will fail.

TC1 on the IF Unit sets the level of the CAR Unit signal to the digital display. Adjusting TC1 will not fix the problem you are experiencing on 10 meters. Although the CAR Unit signal is used on all bands, the CAR Unit signal is not band specific, meaning there isn't a different CAR signal for each band. Adjusting TC1 on the IF Unit will not fix the problem you are experiencing on 10 meter. Adjusting TC1 will affect ALL bands simultaneously as you have found out.

The problem you are experiencing on 10 meters appears to be an improperly adjusted VCO Unit 10 meter (all 10 meter settings) VCO Oscillator in the PLL Unit. The VCO Unit adjustments are covered on page 52 of the 820 service manual under "Adjustment of VCO unit". Table 2 on page 53 lists all of the VCO oscillator frequencies and each VCO oscillator coil. The 10 meter VCO oscillator coils are T7 thru 10.

Each band has an individual VCO crystal that is selected by the band switch. The 10 meter VCO crystals are located on the PD Unit and their individual crystal frequencies are as follows:

28.0 = 33.5Mhz
28.5 = 34Mhz
29.0 = 34.5Mhz
29.5 = 35Mhz

I recommend pulling the PLL Unit and checking each 10 meter VCO crystal on the PD Unit to ensure the crystals for all 10 meter positions have the same frequencies listed above. If the 10 meter VCO crystal are "lower" in frequency then a previous owner had the 820 modified to operate on 11 meters or a frequency band other than the ham bands.

Hello David,

A "constant" ALC indication while operating sideband (USB or LSB) is not required. If you have been lead to believe there should be a constant display of ALC during sideband transmissions then you have been mislead.

ALC is produced ONLY when grid current flows in the final tubes and this can ONLY occur when the level of RF from the driver tube is at a level that causes the grids of the final tubes to swing "positive". Then and ONLY then will ALC be produced.

When operating sideband, set the meter switch to ALC and while speaking into the microphone from a distance of 1 to 2 inches in a normal level of voice, adjust the MIC gain so the ALC meter just "starts" to "flicker" above zero. This is the point of maximum peak RF output. Any further increase in the MIC gain will produce ALC which will cause a "reduction" in RF output, NOT an "increase" in RF output. ALC is there to help keep from over driving the final amplifier and causing splatter (adjacent frequency interference).

Don't be fooled because your watt meter may NOT be displaying FULL OUTPUT. Only PEAK watt meter can display PEAK output. Most watt meters are average watt meters and when the transmitter is adjusted properly the typical RF output displayed on the average watt meter will be 20 to 30 watts at most. This is normal and should NOT be considered a problem or improperly adjusted transmitter.

As for the S meter not zeroing when adjust VR1 on the IF board, either R41 (15K 1/2 watt) has changed values or VR1 is bad. Clean VR1 and readjust as stated in the 520 service manual. Did you perform the complete S meter adjustments in the 520 service manual or just adjust VR1?

The jack is actually a shorting jack that closes (grounds) the keying line in the radio when you remove the plug.
A radio with no key plugged in will key constantly when you are in transmit mode with vox or transmit switch on.
The plug is a simple onc circuit plug, sleeve ground & tip key hot.

Randy,

Forget about the "Tip", "Ring" and "Sleeve". All you need is a cheap simple 1/4" MONO plug with the key wired across the plug. A 1/4" mono plug will only have a "TIP" and a "SLEEVE".

If you have a 1/4" "stereo" plug, wire the key across the "TIP" and the "SLEEVE", the same as you would a 1/4" MONO plug.

It doesn't matter which straight key terminals you connect to the 1/4" mono or 1/4" stereo plug terminals. The key simply operates as a SPST "N.O." switch.

I've wondered about this at times. The manual specifies using a screened lead for the key but the the screen is used as a conductor. So how does it act as a screen?
Guitar lead works well as it's nice and flexy.

> > I have a TS 520S that works with good output, The processor works fine, but when I

switch to alc, it is intermittent in output. It works sometimes, and then as you talk, it slowly drops in output. Sometimes you have to get real close to the mic to get any output at all, yet when I switch it to RF, there is plenty of power out. Also the S meter will not zero even when you set VR1, can't set it on zero with the antenna disconnected. I am using a dummy load for adjusting the radio. can anyone help with troubleshooting this problem? Thanks for reading this post, Hope to hear from someone, 73.

Topic: 30837 Message: 30862

I couldn't tell if you were talking about a remote VFO or not.

The TS-520 series do not have a three prong Edison Plug on them this they depend on the installer connnecting earth(ground) to each chassis.

Each TS Series component needs an earth connection from the rear chassis wing nut ground connection to earth(ground).

You might have some stray voltage running around causing a ground loop which you hear thru the speaker.

Please post the fix when you figure it out.

Good luck.

I have a TS-520 with the 12V-120V option installed.

I have the instructions for jumping the 120V socket for 12V operation but it doesn't make sense to me, (it doesn't take much to confuse me these days...lol

Does anyone have a more detail tutorial or pics on how to wire a 12V plug for 12V operation of a TS-520. I searched the site and didn't find an old post addressing this topic.

Thanks for your help.

You may also need to adjust the "ring" some
and if is is like the one I have for 6m there
is a small coax stub that may need trimming as
well.

Jeff will the top section of the Ringo adjust longer and shorter?. In other words will it slide in and out of the larger diameter tubing or is your Ringo constructed with one piece of tubing it's entire length?

If it is adjustable I would shorten it a few inches and then check SWR or use a antenna analyzer. The matching devise will take some adjustment also.

That's your starting point, now its time to experiment. Good luck..

I had forgotten that the CB frequencies were popular in Australia

30869. Now meter deflection when peaking the alc/drive

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-17 17:13:41 UTC
From: Simon Taylor
Topic: 30869 Message: 30869

Hi guys, I have owned a ts520 for some months now and am really enjoying it! I have tried it on all bands, and can get full output on 3.5, 7, 14 and 21 mhz. However on 28, 28.5 and 29.1, I can get no deflection on the alc reading when trying to peak the drive control. Is it time to replace the drivere tube?

I am sorry if this has been discovered in previous years/months.

Kind regards,

Simon

From: w5rkl
Topic: 30869 Message: 30870

Hi Simon,

Perform the following with the 520 connected to a 50 ohm dummy load that has a power rating of at least 300 watts.

What power output do you get on any 10 meter segment (band switch setting)?

You can tune the transmitter in CW mode. If you have a CW key plugged into the CW socket, either remove it from the CW socket and flip the SEND switch UP or turn VOX ON and press and hold the CW key down (transmitter will activate either way).

Set the CAR control between 10 and 11 o'clock.

Set the meter switch to IP.

Key the transmitter using one of the methods indicated above and quickly adjust the DRIVE control for maximum IP indication.

Adjust the PLATE control for a "dip" (reduction in IP current). At this point you see power output indicated on your watt meter, if your dummy load has a watt meter. If not, switch the 520's meter switch to RF and the meter should indicate a higher than zero indication. None of the meter scales are used with the meter switch set to RF. The meter "pointer" simply rises above zero (far left) as power output increases and falls back towards zero with RF power output decreases. The "RF VOLT" control on the side of the 520 controls the meter's RF setting but the "RF VOLT" control does NOT control the actual RF output from the 520's transmitter.

Alternate between the PLATE control (dip) and LOAD control (Peak RF output), until there is no further reduction in IP current (PLATE control dip adjustment) and no further increase in RF output (LOAD control adjustment). At that point the transmitter is fully loaded and ready for use.

Release the CW key or flip the SEND switch DOWN (unkeys the transmitter), depending on which method you use to key the transmitter in CW mode.

Again, what power output do you see on any 10 meter segment?

The above tuning procedure should be accomplished "quickly" since full screen voltage is applied to the final tubes in CW mode. If necessary, unkey the transmitter between steps to allow the final tubes to cool down, typically 30 to 60 seconds is sufficient to cool the final tubes.

Since you have normal RF output and what appears to be normal stable ALC indication on the other bands, the driver tube does not need replacing nor do the final tubes need replacing.

You may consider performing the DRIVER COIL adjustment on the COIL PACK Unit. This adjustment must be performed as outlined in the 520 service manual. You can't just adjust 10 meter driver coils, there is a sequence of steps you must follow. If you adjust only the

10 meter coils without following the sequence, the other bands will be affected resulting in a change, reduction, in RF output on the other bands. Therefore, perform the procedure as outlined in the service manual.

73s
Mike

I had a six meter Ringo and the top section was slid into the lower section
and secured with a clamp.
If you have a good match on the original operating frequency you should not
touch the matching device.
All you need to do is shorten the top a few inches at a time, checking each
time, until your SWR minimum is where you want to be on the band.

My TS520 had hardly any ALC reading on 10M when it was new out of the box, adding another 40 years to lthat and it only puts out about 55-60 watts on 10M, I tune it with the Plate Current position of the meter and a watt meter. It does fine.

> Adjust the PLATE control for a "dip" (reduction in IP current). At this point you see power output indicated on your watt meter, if your dummy load has a watt meter. If not, switch the 520's meter switch to RF and the meter should indicate a higher than zero indication. None of the meter scales are used with the meter switch set to RF. The meter "pointer" simply rises above zero (far left) as power output increases and falls back towards zero with RF power output decreases. The "RF VOLT" control on the side of the 520 controls the meter's RF setting but the "RF VOLT" control does NOT control the actual RF output from the 520's transmitter.
>
> Alternate between the PLATE control (dip) and LOAD control (Peak RF output), until there is no further reduction in IP current (PLATE control dip adjustment) and no further increase in RF output (LOAD control adjustment). At that point the transmitter is fully loaded and ready for use.
>
> Release the CW key or flip the SEND switch DOWN (unkeys the transmitter), depending on which method you use to key the transmitter in CW mode.

>
> Again, what power output do you see on any 10 meter segment?
>
> The above tuning procedure should be accomplished "quickly" since full screen voltage is applied to the final tubes in CW mode. If necessary, unkey the transmitter between steps to allow the final tubes to cool down, typically 30 to 60 seconds is sufficient to cool the final tubes.
>
> Since you have normal RF output and what appears to be normal stable ALC indication on the other bands, the driver tube does not need replacing nor do the final tubes need replacing.
>
> You may consider performing the DRIVER COIL adjustment on the COIL PACK Unit. This adjustment must be performed as outlined in the 520 service manual. You can't just adjust 10 meter driver coils, there is a sequence of steps you must follow. If you adjust only the 10 meter coils without following the sequence, the other bands will be affected resulting in a change, reduction, in RF output on the other bands. Therefore, perform the procedure as outlined in the service manual.

Hi John,

Thank you for your reply. I can manage around 50 watts maximum. Do you think this could be improved with a new set of valves?

30877. alc/drive problem with ts520

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-17 17:21:54 UTC
From: Simon Taylor
Topic: 30877 Message: 30877

Hi guys,

I purchased a ts520 several months ago and have had great fun operating on the 3.5, 7, 14 and 21 mhz bands. However with the sunspot cycle improving, I thought I would try my hand on 10 metres.

However, when peaking the drive/alc in the tune up proceedure on the 28, 28.5 and 29.1 bands, I cannot get any deflection on the meter, even with the carrier control fully advanced. IP is correct at 60ma and HV reads around 750.

What do you guys think the problem may be? Is it time for a new set of tubes?

I am sorry if this topic has been covered many times before, but I would appreciate your help.

Regards,

Simon

Simon,

Did you try the COIL PACK adjustment I suggested earlier in the 520 service manual yet? Don't buy new tubes just yet before you check and if necessary, perform the COIL PACK adjustments in the 520 service manual.

I am going to sit on the sidelines and follow this one, as I just bought this radio as well a month or so ago, and am still learning my way around. Took me three days to check for the darn jumper on back between pin 8 and 9. Now I am trying to figure out how to interface to computer for better use.

On topic though, have you a copy of the service manual as well as the operating manual? If so I would work through that first. Have you had the cover popped open yet? I had to remove a couple crystals cause of some dumb IDIOT insisted on using this on 11 meters, while it was tuned for it, it gave me hell getting back to proper setup.

You will need the DS-1A converter installed on the back...
You then rewire an AC Jones to a DC Jones by the instructions in the manual...

Simon:

Kenwood Service Bulletin No.21 from 1977 says:

"No ALC meter action on 10 meters: This is normal for TS-520."

My own TS-520 has no ALC indication in tune mode on 10M at all. And nonetheless it puts out 95W on CW into my dummy load on 10M with an SWR indication of 1.4 and a CAR setting less than halfway up the dial.

Now, some people claim they get all kinds of ALC in Tune mode on 10M. But if it works I would not worry about no ALC on the meter.

Hello Chris, Simon, and others,

More often than not operators tend to jump to conclusions in situations such as this and focus primarily on tube replacement. While there are some cases where tube replacement is warranted, quite often tube replacement is not the source of the problem.

A weak driver tube will exhibit the same symptoms on all bands, not just one band. A symptom of a weak driver tube is instability in the drive signal to the final amplifier. That means as the tube warms up (typically after 5 to 10 minutes) the RF output will become less which leads to lower RF drive to the final tubes, hence a reduction in RF output to the antenna. A quick way to tell if the driver tube is weak, watch the ALC meter in TUNE mode "AFTER" the DRIVE control achieves a peak ALC indication. If the ALC meter starts to fall back toward zero either quickly or slowly, the driver tube is weak, replace it. If the ALC meter remains stable and does not fall back towards zero the driver tube is good and does NOT need to be replaced.

Simon, you said the 520 appears to be operating fine on the lower bands, 80, 40, 20, and 15, but not so on 10 meters. I take that to mean the 520 is producing good ALC in TUNE mode on those bands when adjusting the DRIVE control for a peak meter indication. What you did not say is whether or not the ALC indication in TUNE mode on the lower bands after achieving the peak ALC indication was stable or not. You should tune the 520 up on those lower bands and watch the ALC meter for a few seconds after you achieve the peak ALC indication to determine whether the ALC indication is stable or whether it starts to fall back towards zero either slowly or somewhat fast. This will tell you whether or not the driver tube is good or bad.

If you find the peak ALC indication in TUNE mode is stable on the lower bands then the driver tube is not the source of your problem.

As I said you should check the ALC indications as I outlined them above plus the driver's COIL PACK alignment adjustments in the service manual before spending any money on tube replacement.

The final amplifier 60ma "IP" meter indication and final amplifier's HV indication has nothing to do with the driver tube's ability to produce sufficient RF signal to the final tubes for an ALC indication in TUNE mode.

Hi Mike,

I will try the coil pack adjustment first. This will have to wait a week or two. I am busy with work and the XYL has me decorating the house this coming Easter weekend. Then we have a public holiday and street party for the forthcoming royal wedding. Followed by me attending my local radio club's field trip to Tywyn in north west Wales to operate GB8MD for International Marconi Day. It is one very busy month!

However, thank you for the advice and I shall cvertainly try this before spending any hard earned cash!

Subject: Re: [TS-520_820_530_830] Re: "Normal" Mic Gain

Hi Mike--I intentionally did not mention the "processor" settings. What I described is with the processors off on both 530 and 830. My MC-60 has no internal pre-amp. I believe the MC-60A mic has an internal pre-amp? I have used both processors on both rigs and they both work well. I set the 830 processor pot to around 1200 to get around 6db on the "compression" scale of the meter. I have monitored and it clearly adds punch, but would be easy to overdrive.

I just wanted to find out where 830 owners using an MC-60 mic typically set their mic gain at without any processing. As I mentioned at 1:00 (6) setting on mic gain pot I have to "eat" mike to get ALC meter to begin (blip) up. This is much higher setting than is required on my 530SP. This may be normal? I will take a closer look at the two mike pre-amp circuits to see if there is a design reason for this. I see that the processors are very different with the 830 using RF clipping.

Mike --appreciate your questions and quick response. It is not a big problem. I just want to make sure rig is operating as it should as I have no operational experience with 830s. Someone told me I should be using a MC-50 mike with the 830. Doesnt sound right to me. Maybe I will inject 1000hz audio from audio generator into mike jack and run some comparisons?

TNX--Terry

Subject: [TS-520_820_530_830] Re: "Normal" Mic Gain

Hello Terry,

You didn't say whether you are using any transmit audio processing with both transceivers (Processor switch turned ON). You also didn't say whether the MC-60's internal amplifier is turned ON or OFF.

Since both transceivers have the same 500 to 50K ohm microphone impedance, it doesn't really matter what impedance setting the MC-60 is set at.

The TS-530 transmit audio processing is an "ON/OFF" setting, no front panel processing level adjustment other than the MIC Gain. The TS-830 on the other hand, has a separate audio processing adjustment, upper left corner above the meter, to vary the level of audio processing. Therefore, the 830's audio processing adjustment should be set with the MC-60's internal amplifier turned OFF.

If the MC-60 internal amplifier is turned ON and both transceivers have transmit audio processing turned ON, that's not a good combination. Use either one or the other, not both.

Daniel,
Thanks for the reply, I always check resistors before I install them in a circuit to make
sure they are the correct resistance and within tolerance. Burned too many times
in the past. HV on the meter was around 850V, and a bit higher on the DMM when reading off the HV to the finals. Still have to check the other voltages
and check the AF Relay as Mike suggested (also Thank you Mike for the tip).

I did not know that about the ALC for 10M, thanks, now I wont panic when I pay attention to that portion.of the radio. I tend to monitor my voltage more then anything else. I definitely notice this isnt the FT-101E I originally had!

Start with the IPA tube (12BY7) it seems to help most on 10M low drive problems.. Do a touch up on the alignment of the 10 M coils also.
I worked many VK/ZL/S. Pacific islands with the 520 running 60 W on 10M SSB here in MI.

There is no way you can control the TS520 with a computer, like most modern rigs do.
Even my TS440s, 20 years neklwer, requires mods with a special IC set to do computer control.
My 520 has worked fine for almost 40 years with no computer attached :D

Subject: Re: [TS-520_820_530_830] Re: "Normal" Mic Gain

Hi Mike--I intentionally did not mention the "processor" settings. What I described is with the processors off on both 530 and 830. My MC-60 has no internal pre-amp. I believe the MC-60A mic has an internal pre-amp? I have used

both processors on both rigs and they both work well. I set the 830 processor pot to around 1200 to get around 6db on the "compression" scale of the meter. I have monitored and it clearly adds punch, but would be easy to overdrive.

I just wanted to find out where 830 owners using an MC-60 mic typically set their mic gain at without any processing. As I mentioned at 1:00 (6) setting on mic gain pot I have to "eat" mike to get ALC meter to begin (blip) up. This is much higher setting than is required on my 530SP. This may be normal? I will take a closer look at the two mike pre-amp circuits to see if there is a design

reason for this. I see that the processors are very different with the 830 using

RF clipping.

Mike --appreciate your questions and quick response. It is not a big problem. I just want to make sure rig is operating as it should as I have no operational experience with 830s. Someone told me I should be using a MC-50 mike with the 830. Doesnt sound right to me. Maybe I will inject 1000hz audio from audio generator into mike jack and run some comparisons?

30895. WTB Power Cord

Date: 2011-04-18 22:39:05 UTC
From: Dennis
Topic: 30895 Message: 30895

I am picking up a basket case TS 520 later this week. I will need a power cord at least to do a evaluation. Does only one have one in their junk pile of wire?

I know where I can get a new one but I have to try this first.

Thanks
Dennis n5dpk

30896. good operating practive

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-19 02:12:06 UTC
From: kevin
Topic: 30896 Message: 30896

I am trying to get a handle on good operating practice concerning the Mic setting of my rigs. I have NOT used processing at all because I am afraid that I will overdo it until I understand it better. I am a fairly new ham and learning more everyday.

On my 830 with a MC50 I do not need to turn the MIC knob up too much to get the ALC needle to start to flicker, In the past I have adjusted it so that is stays within the band on the meter. As I now understand it that is far too much and I should adjust it downward. Am I correct when it looks on a PEP meter that I am not getting as much wattage out when it is turned lower? If I am right am I trading good correct audio for wattage and coming out ahead?

I have a 520S that I use in a second QTH and I am using a Heil Pro Set Elite with and I have to turn the MIC knob up quite a bit further to get the needle to move. I assume this is because they are two different mikes with different operating characteristics.

Once I get this figured out what do I need to know about using compression?

Hi Kevin,

You're not trading good audio as much as reducing splatter.
Regardless of your audio quality once your ALC meter starts
indicating significant or constant deflection your PA is being
controlled by the ALC circuit and your output power IS being reduced.
I spent the weekend on my TS520S working 40m all over Australia with
reports of excellent audio quality and 5x9+ signal reports and the
ALC meter was barely registering. Please take a look at W5RKL's
excellent ALC explanation from April 17 on this forum.

With regard to compression, as long as you've set your mic gain
correctly the compression will also be OK. If you're unsure get on
air with someone you trust and ask them to give you a fair and
unbiased report on your audio with and without compression. Ask them
to listen off frequency a little and see if your signal gets wider
with compression on.

I am sorry, I meant for digi modes, through Mic plug. I already know the radio well enough to know It isnt being controlled by anything other then a loose nut at the controls!
I miss my old Yaesu FT-101E, but this has some temperament of its own as well.

Mike;
In the service manual, page 33, when I go through all of the steps for setting the base current adjustment,
am I supposed to hit the "send" switch? When I do, I can then set the bias to the 60ma level.
AF Relay is ok, but when I was taking this all apart to pull the AF board and the relay out, I found
electrical tape with a cut wire taped up but not connected - This went to AF Connector #6,
pin 4 (dark Blue wire) ((TOF??)). Fixed that with some solder and heat shrink and look like
this is now working.

Thanks again for the tip on the AF Relay - what lead me to the cut wire.

Chuck,

That cut wire enables transmit on the WARC bands. The WARC band mod instructions are on page 28 of the manual I have. It is under section 6.5 TRANSMITTING ON WARC BANDS. By restoring that connection you have disabled the ability to transmit on the WARC bands.

BTW, you aren't the first one to find that cut wire and restore it!

73,

Ken, WA2LBI

From: w5rkl
Topic: 30896 Message: 30907

Kevin,

Tune across the bands and find a very loud station, especially a station that sounds as though the operate is talking much louder than normal and the audio sounds as though the operator has the microphone pressed up against his/her lips. Tune above or below that station's frequency until you can no longer understand them. Continue tuning slowly and you will no longer hear the audio but you will hear a rather "raspy" sound as the station continues to transmit. The "raspy" sound is splatter. When the station no longer is transmitting the "raspy" sound will disappear until that station begins transmitting again. I hear stations splatter quite often on 80 and 40 meters.

When you tune onto a loud splattering station's frequency you can easily hear the distortion in their signal. When I say "loud" I'm not referring to the station's signal strength but rather the loudness of the audio. For what ever reason these stations tend to believe the LOUDER the BETTER! If you're lucky and start listening at the beginning of the round table conversation, you will hear one or more stations tell the LOUD offending station, "you sound great!!". I have listened to stations like that and even heard one station in the group tell the offending station their audio is too loud and distorted, to back off the microphone gain and talk farther away from the microphone.

Operator's need to start learning how to operate their station properly. Operators also need to start paying attention to what the ALC meter is actually telling them. Operators also need to learn what ALC is, when and how it is produced, and what ALC is actually used for. Unfortunately, the operator's manual is misleading in its brief description of the ALC meter switch setting. I believe many, not all, inexperienced operators become mislead by the brief and incomplete discussion of ALC in the operator's manual. As I always say, it's not how LOUD you are but how clean your transmit signal is. There's absolutely no excuse for an operator to improperly operate their amateur radio station!!

73s
Mike

Kevin

At the REDCLIFFE RADIO CLUB where i am a member, they built STUB FILTERS FOR the JOHN MOYLE compition day .

These are placed between the AMP and the antenna. and really work at reducing harmonic interference and noise.

however they are band specific, and will only work on aspecific frequency . You would require 1 for each band being operated on.

Topic: 30909 Message: 30909

Maybe a dumb question, but other then a easy way to connect the ground to your coax, does a lightening arrestor have anything else in it?

I have ground to my radios, meter, power supply.. etc.. Would adding a lightening arrestor do anything that the existing grounds don't give me?

Thanks
Kent.

Hi Kent,

In normal operation the lightning arrestor doesn't connect your cable to ground. It's only when....., sorry, if, there is a lightning strike, the lightning arrestor provides an easy path to ground instead of the full strike travelling to your station. You can use commercially made gas filled units but if you don't want to pay anything at all, an old vehicle sparkplug in a waterproof housing will do the trick.

30911. TS-820 Voltage Problem on IF Unit

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-20 11:19:06 UTC
From: ae5uu
Topic: 30911 Message: 30911

Good morning all,

This is a resubmission of my post of last week; I did not get any responses, and I sure could use some help. Thank you for taking the time to read this.

I have been fighting a stubborn voltage problem for some time. I would appreciate some help.

First a new distraction with symptoms:

60ma idle is correct.

In TUN, no PLATE current registering on IP meter setting.

In CW, no current showing with adjustment of LOAD and PLATE controls

No transmit (NONE OF THESE SYMPTOMS WERE AN ISSUE UNTIL TODAY WHEN I REPLACED FINAL UNIT R-2, R-3, R-5, R-6. I ALSO REPLACED L-1 AS PER KIT VALUE (6.8UF, 500MA) SUPPLIED AS KIT FR-100 BY K4EAA, BUT NOW NOTICE THE THE VALUE FOR L-1 LISTED IN MY PARTS LIST IS 470UF, SO I WILL SWAP BACK L-1 AND HOPE FOR THE BEST)

ALL THE ABOVE IS NOT MY MAIN PROBLEM. MY MAIN PROBLEM IS DETAILED BELOW:

Meter does not increase reading when RF GAIN is rotated CCW (although the receive audio is reduced gradually as it should be.)

In TUN, no ALC reading with DRIVE control on ALC meter setting.

-6vdc bus reads +0.59vdc

+3.3vdc bus reads 3.3vdc with IF UNIT IF3 unplugged, +6.4vdc when IF Unit IF3 is plugged in.

No S Meter reading.

BELOW IS A LISTING FROM ALL MY VOLTAGE TEST POINTS. ALL APPEAR CORRECT WITH THE POSSIBLE EXCEPTION OF THE RECTIFIER UNIT "SG" AND "STB" AND THE HV UNIT "HV" TERMINAL (I DON'T KNOW WHAT THE VALUES SHOULD BE.)

+14vdc

AF-AVR board AF1 pin 3
IF Board IF1 pin 3
Fix-Vox Board FX3 pin 3
Relay Board RL1 pins 7-12
RF Board RF1 5
Rectifier Board Terminal "14"
ALL POINTS YIELD PROPER VOLTAGE

+9vdc

IF Unit IF1 pin 5
CAR Unit CJ2 (Mode switch set to TUN, CW, LSB, FSK,and SSB)
PLL Unit PLL2 pin 3
FIX VOX Unit FX3 pin 1
Relay Unit RL1 pins 1, 2, and 3
Relay Unit RL2 pins 10 & 14 (note: pin 14 has no wired connection)

HV Unit FSB Terminal +260vdc

210 Terminal +260vdc

800 Terminal +952vdc

HV Terminal +43vdc

Final Unit PD2 Terminal +260vdc

FG Terminal -100vdc Receive (spec.)
-100vdc (actual)
-55vdc Transmit (spec.)
-54vdc (actual)

SG Terminal +255vdc Receive (spec.)
+260vdc (actual
+210vdc Transmit (spec.)
+225vdc (actual)

The following parts have been replaced, in addition to all electrolytic capacitors on all boards:

1) AF-AVR Unit VR-1, VR-4, D-5, Q-4, Q-5, and Q-6
2) IF Unit Q-15, Q-16
3) IF Unit D-18, D-19, D-20, and D-21
4) IF Unit C-70, C-72, and C-142
5) IF Unit R-66, R-145, and R-146
6) PD Unit C-14, C-15
7) FIX-VOX Unit Q-13
8) HV capacitors C-21, C-22, R-6, R-7, and 2 each 0.01uf (C-14 through C-17 type)

Notes: AF-AVR Unit R-9 and R-26 not installed (jumpered by factory)
C-29 installed according to schematic (polarity is marked wrong on board)

FIX-VOX Unit C-32 replaced with 3.3uf, 50wv factory spec., was 1.0uf in my radio

IF Unit C-43 as built is electrolytic, not as listed in parts list

C-75 as built is 1.0uf, 50wv, not .01uf as listed in parts list

Firstly, I need to correct my +3.3vdc and -6.0vdc problem. Then I intend to look at Q-5 on the RF Unit. Measured at RF3, pin 6,the reading is 5.2vdc in Receive. In Transmit it changes with application of the DRIVE control. It does not change with application of the CAR control.

I know that this is a complex posting; your assistance would sure be appreciated before I pull the rest of my hair out.

73,

Russell

Hi Kent,

W8JI has an excellent write up about grounding.

http://w8ji.com/ground_systems.htm

Hello Russell,

You have changed a significant number of components which is going to make it very difficult to diagnose your problems.

You are incorrectly referring to RF chokes using the wrong unit of measure "uf". "uf" is "microfarad" which is what the typical unit of measure for capacitors. Inductors unit of measure is the "uh" (microhenry) which includes RF Choke, air and iron core coils. This may seem trivial but when referring to component's unit of measure it's important to use the correct unit of measure.

You indicated that you changes the RF chokes in the Final Unit using Ken's (K4EAA) final amplifier rebuild kit components. Were the original RF chokes found to be bad (overheated, burnt, cracked, broken coils etc)? If not then I would not recommend replacing them just because a kit you purchased from Ken included an RF choke. Choke L1 on the Final Unit's sole purpose in life is to keep RF off of the bias supply "FG" connection between the Final Unit and the RF Unit. It serves no other purpose what so ever.

The -6VDC you say is missing, originates from the FIX VOX Unit's DC to DC converter which consist of Q13 and T2. You might check Page 59 in the TS-820 service manual.

"STB" is the CW Side Tone Bias voltage that is applied to the FIX VOX Unit (X5--1350-00). The only time STB is required is to bias the CW side tone oscillator in CW mode. The Mode switch, when placed in CW mode, enables the CW side tone. Shorting the CW key terminals (CW key pressed) at the CW socket causes the CW side tone oscillator to produce an audio tone that is fed from the FIX VOX Unit to the AF AVR Unit so the operator can hear his/her fist. If the STB voltage is missing at the FIX VOX Unit plug FIX3 pin 10 then the CW side tone oscillator will not work, providing all other CW side tone enable voltages/settings are correct.

You said you have 60ma of IP idling current yet you then say there is no IP current in TUNE and CW mode. If you have 60ma of idling current then the final amplifier bias circuit is working and you should see idling current in TUNE and CW mode. Naturally the idling current level will be less in TUNE mode since resistor's R5 and R6 (56k 1/2 watt each) lower the final tube screen voltage. In CW mode, with the transmitter keyed but the CW key is not pressed, the idling current will be slightly higher, approximately 70ma, which is normal.

The final amplifier's bias voltage is controlled by the state of RF Unit's "RLK". "RLK", when the Relay Unit's relay terminals "RL-13" are switched (relay energized), grounds the "VR3" terminal of the bias pot. This cause a change in the bias voltage to the final amplifier grids to become "less negative", turning both final tubes ON. If you have not measured the bias voltage on the final tubes in ALL modes between receive and transmit then I recommend you do that. You can measure it at the final unit's "FG" terminal. All you have to do is place the Mode switch in each position and flip the "SEND" switch UP for transmit and DOWN for receive. The voltage at the "FG" terminal should be approximate -98VDC or so in receive and -60VDC or so in transmit. This voltage will be stable, no vary, when there is no RF applied to the final tubes. If this is what you see then the bias voltage is

switching as it should. The meter is not only controlled by the meter switch in transmit but also by the T/R relay terminal RL-3. The T/R relay is located on the bottom between the final amplifier PC board and the rear panel inside a metal enclosure.

You say rotating the RF gain control in receive to remain at zero but the receiver itself appears to have less sensitivity (lower audio output). The Relay Unit relay terminals RL-14 control what is displayed on the meter, S unit and movement of the meter by rotating the RF Gain control and meter switch positions in transmit.

The 820 is noted for having plug and pin connection problems. The wire connections in the plugs can quite often fail which are very difficult to find. This can lead you in the wrong direction, replacing components that don't need to be replaced and chasing your tail. The pins on the boards themselves can also have breaks in the PC board foil runs, it doesn't take much to create a break/crack in a foil fun. I recommend you cease replacing components and thoroughly check the plug to pin connections as well as look for cracked/broken PC board foil runs from the board pins. Use the individual schematics and the high resolution schematic available at Gordon's website and also from Ken's website. Ken has a 3meg high resolution main schematic for the 820.

http://www.k4eaa.com/820_main.pdf

I recommend using it in conjunction with the 820 service manual's individual schematics to diagnose your problems.

Topic: 30911 Message: 30916

Since you have replaced a lot of components not only on the Final Unit both but also on other boards, I recommend you closely inspect the PC board foil runs and use an ohm meter to check continuity between components. For example, if you replace a diode and the cathode end of that diode connects to a resistor elsewhere on the board. You should check continuity between the diodes cathode lead and the resistor to ensure that foil runs is not cracked/broken. It doesn't take much to break/crack the foil runs. Bending the board slightly when handling, for example, can crate a break in a foil run. Pushing too hard or rocking/bending board pins back and forth can also create breaks in foil runs. I recently worked on an IF board in a 530 where one plug socket "rocked" back and forth on the board. I checked continuity between the pins and found broken foil runs all because the socket rocked back and forth. The break was at the socket pins themselves and no matter how much I cleaned the connection and applied proper solder to the pin(s) the break was still there. I had to use a short piece of wire to "jumper" the broken foil run to fix the problem. The problem "appeared" to be a bad switch contact or faulty capacitor. The problem symptom was the receiver's "SLOW" AGC switch setting didn't work. This could have easily caused one to replace the switch OR replace the capacitor which would have NOT fixed the problem. The problem was the broken foil run on the plug's pin. This is why it's very important to ensure components are actually bad before replacing them.

30917. Re: TS-820 Voltage Problem on IF Unit

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-20 15:13:14 UTC

Topic: 30911 Message: 30917

I tried posting an additional comment to my previous response but it appears it got lost in the "bit bucket" behind the processor.

Another thing you should look for is breaks/cracks in the PC foil runs. The breaks/cracks can occur at pins under the solder connection, along the foil run itself, or just a centimeter from the component junction/connection to the board. Finding these cracks and breaks can be a time consuming task. If I suspect a break in a foil run I use an ohm meter. For example, if I suspect a break between a diode's cathode and a resistor, I check continuity between the diode's cathode lead and the resistor. If there's a break/crack in the foil, I look at the entire foil run using a bright light shown on the component side and view the foil run using a magnifying glass. Some, not all, breaks/cracks in the foil runs can be found this way. If I can't see a break then I check continuity between the actual component leads which will tell you if the foil run between the 2 component leads is good or bad. If found bad a small gauge wire is used to jumper across the break and fix the problem.

Another area is broken wire connections in the plugs themselves. This can happen without you noticing it. The wires are connected by "crimping". If the wire breaks at the crimp then there a good chance the connection will be lost.

Bad/poor soldering at pins on the boards can also affect the connection. The pin connections on each board should be thoroughly checked to ensure the connection is good. Loss of one simply "control" voltage can affect a number of circuits.

That's why replacing components should only be done when a component has been found to be defective/bad during troubleshooting. Replacing components in a "willy nilly" fashion will, in many cases, not change the symptoms nor will it fix the problem.

> Hello Russell,
>
> You have changed a significant number of components which is going to make it very difficult to diagnose your problems.
>
> You are incorrectly referring to RF chokes using the wrong unit of measure "uf". "uf" is "microfarad" which is what the typical unit of measure for capacitors. Inductors unit of measure is the "uh" (microhenry) which includes RF Choke, air and iron core coils. This may seem trivial but when referring to component's unit of measure it's important to use the correct unit of measure.
>
> You indicated that you changes the RF chokes in the Final Unit using Ken's (K4EAA) final

amplifier rebuild kit components. Were the original RF chokes found to be bad (overheated, burnt, cracked, broken coils etc)? If not then I would not recommend replacing them just because a kit you purchased from Ken included an RF choke. Choke L1 on the Final Unit's sole purpose in life is to keep RF off of the bias supply "FG" connection between the Final Unit and the RF Unit. It serves no other purpose what so ever.
>
> The -6VDC you say is missing, originates from the FIX VOX Unit's DC to DC converter which consist of Q13 and T2. You might check Page 59 in the TS-820 service manual.
>
> "STB" is the CW Side Tone Bias voltage that is applied to the FIX VOX Unit (X5--1350-00). The only time STB is required is to bias the CW side tone oscillator in CW mode. The Mode switch, when placed in CW mode, enables the CW side tone. Shorting the CW key terminals (CW key pressed) at the CW socket causes the CW side tone oscillator to produce an audio tone that is fed from the FIX VOX Unit to the AF AVR Unit so the operator can hear his/her fist. If the STB voltage is missing at the FIX VOX Unit plug FIX3 pin 10 then the CW side tone oscillator will not work, providing all other CW side tone enable voltages/settings are correct.
>
> You said you have 60ma of IP idling current yet you then say there is no IP current in TUNE and CW mode. If you have 60ma of idling current then the final amplifier bias circuit is working and you should see idling current in TUNE and CW mode. Naturally the idling current level will be less in TUNE mode since resistor's R5 and R6 (56k 1/2 watt each) lower the final tube screen voltage. In CW mode, with the transmitter keyed but the CW key is not pressed, the idling current will be slightly higher, approximately 70ma, which is normal.
>
> The final amplifier's bias voltage is controlled by the state of RF Unit's "RLK". "RLK", when the Relay Unit's relay terminals "RL-13" are switched (relay energized), grounds the "VR3" terminal of the bias pot. This cause a change in the bias voltage to the final amplifier grids to become "less negative", turning both final tubes ON. If you have not measured the bias voltage on the final tubes in ALL modes between receive and transmit then I recommend you do that. You can measure it at the final unit's "FG" terminal. All you have to do is place the Mode switch in each position and flip the "SEND" switch UP for transmit and DOWN for receive. The voltage at the "FG" terminal should be approximate -98VDC or so in receive and -60VDC or so in transmit. This voltage will be stable, no vary, when there is no RF applied to the final tubes. If this is what you see then the bias voltage is switching as it should. The meter is not only controlled by the meter switch in transmit but also by the T/R relay terminal RL-3. The T/R relay is located on the bottom between the final amplifier PC board and the rear panel inside a metal enclosure.
>
> You say rotating the RF gain control in receive to remain at zero but the receiver itself appears to have less sensitivity (lower audio output). The Relay Unit relay terminals RL-14 control what is displayed on the meter, S unit and movement of the meter by rotating the RF Gain control and meter switch positions in transmit.
>
> The 820 is noted for having plug and pin connection problems. The wire connections in the plugs can quite often fail which are very difficult to find. This can lead you in the wrong direction, replacing components that don't need to be replaced and chasing your tail. The pins on the boards themselves can also have breaks in the PC board foil runs, it doesn't take much to create a break/crack in a foil fun. I recommend you cease replacing components and thoroughly check the plug to pin connections as well as look for cracked/broken PC

board foil runs from the board pins. Use the individual schematics and the high resolution schematic available at Gordon's website and also from Ken's website. Ken has a 3meg high resolution main schematic for the 820.

Although I bought my TS-830S used I got all the documents including the
warranty card that indicated the following

Purchase Date 3-1-1985
Serial Number 4100139

There is a serial number close to yours in the following database:

http://groups.yahoo.com/group/TS-520_820_530_830/database?method=reportRows&tbl=4

That indicates the following:

1050150
TS-830S
Oct 4,1981

My father's TS-820 consistently reads 4kHz too high on the analogue scale, which is annoying. I tried to adjust the VFO according to p48 in the Service Manual I downloaded, but I can't figure out how to put a frequency meter across Pin 13 without disconnecting everything else. Not that it matters, as I can't see how I get into the VFO to change L1 or TC1 in the first place. So: what is the accepted way to measure voltages on those pins? And how do I get into the VFO, please? 73 de Robin ZL4IG

If the knob is like my TS520, just hold the center part still when you get the frequency set with the marker or WWV and carefully rotate the numbered outer ring until the proper frequency mark lines up with the pointer.

Mike,

Thank you for your direct and to the point response to my request for help with my "Stubborn voltage problem on the TS-820 IF Unit."

Yes, I have had a lot of trouble with cracked foil runs in this radio. I have inspected them, repaired them, and been annoyed by them, particularly in the IF Unit, where I now seem to spend most of my time.

I previously had numerous problems with the AF-AVR Unit, including bad pins, bad foil runs and failing VR-4 and VR-1 pots. These problems are behind me now, with replacement of the pots, hardwiring AF1 and AF2 directly to the foil (with suitable extra lead length so that I can work on the board if I ever need to again. By connecting a ground connection to the board, I can operate the radio with the board un-installed (which I have found useful for problem solving.) I will send you a photo via regular email.

I replaced all of the electrolytic capacitors by way of preventive maintenance. I understand what you are saying about replacing "good " parts, but I felt comfortable doing this from my experience with other electronic equipment of this vintage (shipboard equipment.) The replacements must have gone OK, because all of my voltage readings (HV and LV) remain as they were before my swap-out. My IF Unit problems remain unchanged, and continue to defy me with or without new electrolytic capacitors throughout the radio. The symptoms are unchanged and the radio doesn't work any better or worse than before, with the exception of Receive sensitivity, which has improved, perhaps because I replaced the two tantalum capacitors on the PD board, C-14 and C-15.

I have had to repair many of the wires in the wiring harness, which I probably broke while moving things around. These old solid wire conductors are of poor quality and very brittle. The people who built these things should have used tinned stranded conductor wire, as we have done at sea for ever. I am sure that you in particular, with your maritime experience, know exactly what I am talking about. Any wire that breaks, I replace with marine grade wire.

The bit about the RF choke units was a typo on my part. I elected not to replace L-1 in the Final Unit; it looked fine, and the replacement in the kit did not appear to be of the proper value for this radio.

I checked the 60ma bias current issue more fully. Rightly or wrongly, I only check for idle bias on whatever sideband I wish to use when tuning. After your comment, I checked it in CW and found 63ma, slightly more than the 60ma that I measure on SSB, just as you said that I would. When checking in TUN mode, however, I show no idle bias current?

I have now measured the bias voltage at Terminal "FG" on the final Unit:

Mode Receive Voltage Transmit Voltage
Spec. Value -98vdc -60vdc
My Readings:

USB -99vdc -53.8vdc
LSB -99vdc -53.8vdc
CW -99vdc -53.7vdc
TUN -99vdc -55.4vdc

Checking my problem of no -6vdc at the IF Unit, I have measured FIX3, pin 14 on the FIX-VOX board and find the same +0.563 that I find at the IF Unit. I have not looked at the FIX-VOX board before, and will look toward Q-13 and T2, as you suggest, to discover why my -6vdc is missing, and is in fact +0.563.

Checking my problem with no increase in Meter reading when the RF GAIN control is rotated CCW (checking Relay Unit RL-14), I find that on RL3, pins 1 and 2 (ALC), I have 6.22vdc when the RF Gain is fully CW and 5.78vdc when it is fully CCW. On RL3, pins 3 and 4 (AGC), I find 6.98vdc when fully CW and 4.02vdc when fully CCW. The RF GAIN control was working and continues to work properly with lower sensitivity (less audio output) when rotated CCW, even though I continue to see no response on the meter.

I am going back to looking for foil breaks on the IF Unit this evening, as well as on all the rest of the boards. If you could give me your analysis of the voltages above, as well as all the HV voltages that I detailed in my last posting, I would be most appreciative.

Thank you Mike.

73,

Russell
AE5UU

Sorry, I didn't explain myself properly: the problem lies in the dial itself, not the rotating ring... it is out by 4 divisions on the dial, not the knob ring.

i know there are stations that have strong signals, hear them complain all the time that someone is splattering. i find in some cases that the receiving station has his or her noise blanker set on or too high causing the problem to magnify in the receiver. do some stations splatter, yes, are some stations just producing a strong signal due to good prop and even if clean will have some fellow griping because of alleged splatter, so there are many factors other than just your splattering om. ron ne0x

As I said before, my TS-520 has no ALC indication on 10M.

And I just cranked it up on 28.475 and, using a dipole antenna strung in my attic here on the East coast of Florida, had a nice clear chat with a gentleman in Tucson, AZ.

Mike, I fixed the fluctuation on the digital display. Seems it needed some contact cleaner on the band switch contacts. Got another question though. I took the knob of the plate adjustment, what should the pointer be at when the plates are fully meshed?

Thanks Joe

There are 3 pins on the plug, one is the 14VDC input source voltage, one is the regulated 5VDC output, and the other is ground.

Thank you Michael.
I have seen the database.
Probably Kenwood made my rig in 1981.
If I find a TS-830 made in late years I buy it.

The LF filter goes after the AMP. The ATU goes after the TX and reduced any harmonics generated by the TX. No need to have 2 LP filters.

When I switch on my 830s, I get a "start-up beep". I find this annoying
especially when I have told the XYL, (asleep in next room) that I have switched
the rig off, and want to re-start it without her knowing. :-)
How can I switch this off?
Jon G4FUT

30929. TS-520 VFO (internal)

From: w5rkl
Topic: 30929 Message: 30930

More than likely the problem is a very dirty VFO variable capacitor shaft to frame connection.

Remove the top cover, take care not to break the speaker cable.

Disconnect all power to the transceiver.

Front panel facing you, the VFO is the metal enclosure directly behind the front panel, in the middle.

Look on the right side of the VFO enclosure and you will see a small metal plate held to the VFO enclosure by 2 Phillips head screws.

Remove one screw, the rear is easiest to remove.

Loosen the other screws 1 turn.

Rotate the plate so you can see the variable capacitor plates.

Look at the rear of the variable capacitor and you will see a flexible "fork" connection. This connection needs to be cleaned.

Give the point where the fork meets the variable capacitor shaft a shot of DeoXit contact cleaner. Rotate the VFO to the end of rotation, both directions, several times.

Next, use generous amounts of canned air, available at Walmart, and
blow air at the point where the cleaner was applied while rotating the VFO knob.

Wait a few minutes then test the 520 VFO for proper operation. If the intermittent operating still occurs but much less, repeat the cleaning procedure.

Jon,

The TS-830 does not have a built in "roger beep" that is heard when the 830 is turned ON. Do you have a CW key plugged into the CW socket, VOX is turned ON, and the Mode switch set to CW? If so, turn VOX "OFF" and set the Mode switch to USB or LSB. Turn the 830 OFF then, after a second or two, turn the 830 on. Do you still hear the "beep"? If not then the CW Break-in (VOX turned ON) is causing the "beep".

Many of the currently used antenna "tuners" are twin T circuits and actually look like high-pass circuits.
 Adding one between a rig and amp would have little effect removing any harmonic content.
The only benifit (?) would be showing the rig's PA circuit a 50 ohm load.

Topic: 30934 Message: 30934

Hello,

I'm in the process of replacing RL-1 on my TS-830S due to an intermittent ALC indication problem. I've got the radio on the bench with the covers off ready to go. I'm scratching my head trying to figure out how the old relay is to be removed from the board so that the replacement can be installed. Can anyone that's done this before offer any guidance on how this is done?

Many thanks in advance,

Joe

The low pass filter referred to in this thread is a "TVI" filter.

A low pass filter does not provide a 50 ohm load to the exciter or amplifier like a 50 ohm dummy load does. A filter is just that, a filter, nothing more, and it is "transparent" to the transmitter and/or amplifier.

Low pass filters are designed to "filter" any VHF and above harmonic radiation from the RF source (exciter or amplifier) to prevent "TVI". Most, not all, older vintage and all modern day transceivers/transmitter, the PI Networks and broadband filters systems provide a significant reduction in harmonic radiation. Therefore, put the filter on a shelf in your shack, you don't need it. Besides, it makes a good conversation piece.

Joe,

The relay on the AF Unit is "soldered" to the board. You have to heat the solder connection, remove the solder from the relay pins, and pull the relay out. You must use a low wattage soldering pencil, 20 watts at the most.

The relay can only be installed on the AF board "one way". That means the pins are arranged on the relay so they only fit one way.

If you have never done this before and/or your soldering skills are not very good, then I recommend you find a local ham with good soldering skills to help you. You can easily damage the board and create foil breaks/cracks that will have you chasing your tail if you are not careful.

Although using headphones will keep the Xyl from hearing the transceiver being turned on and hearing the beep, using headphones will not eliminate the source of the beep and that's what Jon wants to do, eliminate the beep.

Thanks for the response Mike. The biggest problem I see is being able to access the under side of the board to de-solder the pins to begin with. It's tight in there! I just don't want to damage anything because aside from the ALC indication being iffy, the radio works fine.

Topic: 30939 Message: 30939

I have searched the messages and haven't found what I need. I was wondering how hard it is to change the two meter lamps on my radio. Can this be done from the top only or will I have to take the front cover off also. Checked the service manual and it shows how to get the meter out but doesn't show the termination of lamp wires. Any help would be helpful before starting.

Thanks
Robert

Take just the TOP cover off.
Right above the meter are two small Phillips screws. remove these and
the bracket that hold the Lamps will slide back allowing you to change
the meter Lamps.

From: Lou Blasco
Topic: 30941 Message: 30942

The replacement crystals are not for the FIX-VOX board.They are for
the PD board and depending on which band was modified you will have
to replace one crystal on that board. Refer to the service manual for
more details. I haven't worked on an 820 but looking at the service
manual I can see the following;

X7 (33.5MHz) is used for the 28MHz band
X8 (34MHz) is used for the 28.5MHz band
X9 (34.5MHz) is used for the 29MHz band

Once you've replaced the crystal you should run through the alignment
procedure in the manual.

brannola,

I have done 3 fixes of this type of "CB HACK." Go to the home page and look for the photo(s) entitled TS820S CB HACK (WB7UQU). The crystals...most often 3 will have to be unsoldered and removed...most often they are crystals.. X-8, X-9 and/or X-10. they are usually very easy to spot as most of the time they are all silver and don't have a blue plastic shrink wrap on them with the printed frequency...but compare with schematic to make sure....with the proper ones put back in. The PLL/PD box will have to be removed...the AF-AVR screws should be removed also..it makes it ALOT easier to the the PLL/PD unit out. The PLL/PD unit is held in by screws on the side of the chassis (3) and two inside. When you get it back together the PLL/PD unit will need to be realigned. Good luck..it's not too difficult...just a pain.

Joe;
I just went through this on a TS-830S on the bench, although I did not end up replacing
the Relay, I did take the board out of the unit.

You have the five screws in the PCB and three screws (2 on side - 1 in front) on the
metal heat sink which forms an "L" around the board. There will be wiring on a few
pins on the PCB which I tagged and removed. I also marked all 10 of the connectors
on the connector housing and where the connect on the board.

Once you have the board out, it is easy to use solder wick and a light wattage
soldering iron and remove the relay.

As I said, after I had gone through the drill, I removed the cover to the relay
and spray DeOxit on the contacts and moved the actuator arm a few times.
I did this routine a couple of times to make sure the contacts were clean.
That seems to have fixed the problem for me.

Just takes some time removing everything, marking all of the wires/connections
and making sure everything is back in the exact place/pins where it is supposed to go. Also make sure after you are done, you check the voltages on Connector 9 Pin 5, and also on TP6 and the FG pins.

As Mike said, if you are not comfortable with doing this work and de-soldering/
re-soldering the part - Get help from a local ham who does decent repair work.

Good Luck, 73s and hope it works out for you.

Chuck, KJ4GU

30946. TS-820 IF Unit Voltage Problems

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-22 11:49:03 UTC
From: ae5uu
Topic: 30946 Message: 30946

Mike,

Looking for my missing -6.0vdc, I took a look at Q-13 on the FIX-VOX Unit as you suggested. It was bad. I replaced it and now show -6.0vdc on the IF Unit again. So that worked; thank you.

Examining the IF Unit board with a bright light behind it and using a magnifying glass, I found two cracks in the foil run for RFI. I would have never seen them without the glass. These have been repaired.

The big problem remains, as it has all along, that even after all new electrolytics, new Q-15 and Q-16, and confirmation of continuity and no shorts in the foil runs, my 3.3vdc bias rises to 6.0vdc when the IF Unit board is fully plugged in. The voltage returns to 3.3vdc when I disconnect IF3 on that board.

Either I installed Q-15 or Q-16 incorrectly when I replaced them (easy to do as the lead layout is different on the replacement transistors), one or both of them were defective, or I still have a mystery cause for my 3.3vdc problem somewhere on this board.

Is there anything else that you would recommend looking at that might be causing my problem?

Also, during tuneup, I still get no reading in ALC with the Drive control.
Additionally I still have no increase in meter reading when the RF Gain control is rotated CCW. Until yesterday, when I replaced Q-13 on the FIX-VOX Unit, I did have a reduction in receive sensitivity as this control was rotated CCW; this is no longer the case. Rotating the control CCW now has no effect on anything.

In spite of the above, the radio puts out a strong signal with good signal audio reports, and Receive is very sensitive.

Thanks for your help.

73,

Russell
AE5UU

Hi Charles,

Thanks for the details on the how to do this. I see I'm not "the lone ranger" this procedure :)

I think one of my biggest hang-ups on doing this is removing all the connectors the correct way. They don't seem to be "hand tight". I'm decent with a soldering iron but, I want to make sure I get it right as the radio is working just fine with the exception of the ALC indication being intermittent. I don't experience any slow return of receive after transmitting whatsoever. Just no ALC indication at times.

I'll take it slow and careful.

Again, many thanks for the response.

73 with regards,

Joe

Joe;
You may have the same problem I did and although I removed the board from the unit,
I really did not have too for the repair.

If you get a sharpie with a good point, mark each connector on the flat side opposite the
pins. As you look toward the rear with the radio upside down, the connectors start at the
top left as #10 and going right you have #9 and then #8, and coming from the top
down the right side you have #7 through #2. Connector #1 in toward the left of the
board about 1/2 way or a little more down.

These can be pulled out by hand, just be careful and do not break any wires.

Oh by the way, Connector 6, has the dark blue wire on pin 4 cut to enable WARC bands, do not make my mistake and solder it back together.

Take out the screws for the PCB and the metal "L" shaped heat sink and remove the board. VERY CAREFULLY remove the cover to the Relay.
I started toward the top of the board and gently pried off the cover and then removed it.

I sprayed the relay contacts with DeOxit and moved the relay actuator arm carefully a few times, - did this routine three times. Be very careful, as these
are very small fragile contacts and arms.

After I was done with the above, I used some canned compressed air and blew out any excess DeOxit and then let it air dry for a while. While that was drying, I then used the DeOxit on all of the connector pins, and then put the connector on the associated pins on/off several times to clean the male pins and female plugs.

Again used compressed air to dry everything off, and a let it sit for about an hour to make sure everything was dry (DeOxit is VERY flammable).

When I got it back in and together, my problem was solved.
By doing the above, you do not have to remove the wiring to the individual pins on the board.

Fixed my problem with the above (Could not get the 60ma idle current (bias) set prior to this).

By the way, Mike W5RKL,had given me a good tip to check the
relay. With a DMM, Black to chassis ground and the Red lead
to the "FG" post on the AF board, when you flip the the SEND
switch from Receive to SEND you should see a negative voltage
swing from -100VDC in Receive to about -60VDC in SEND.

The FG post is to the left of the RELAY maybe 3/4 of an inch or
so and has a White/Yellow wire from it to the Final Board.

Also, make sure you discharge the HV on the caps since
you will be working with the unit upside down and the HV caps
are just to the right of the AF Board.

Hope this is of some help. Hopefully it will save you some work.

Chuck, KJ4GU

> ALC is produced ONLY when grid current flows in the final tubes and this can ONLY occur when the level of RF from the driver tube is at a level that causes the grids of the final tubes to swing "positive". Then and ONLY then will ALC be produced.
>
> When operating sideband, set the meter switch to ALC and while speaking into the microphone from a distance of 1 to 2 inches in a normal level of voice, adjust the MIC gain so the ALC meter just "starts" to "flicker" above zero. This is the point of maximum peak RF output. Any further increase in the MIC gain will produce ALC which will cause a "reduction" in RF output, NOT an "increase" in RF output. ALC is there to help keep from over driving the final amplifier and causing splatter (adjacent frequency interference).
>
> Don't be fooled because your watt meter may NOT be displaying FULL OUTPUT. Only PEAK watt meter can display PEAK output. Most watt meters are average watt meters and when the transmitter is adjusted properly the typical RF output displayed on the average watt meter will be 20 to 30 watts at most. This is normal and should NOT be considered a problem or improperly adjusted transmitter.
>
> As for the S meter not zeroing when adjust VR1 on the IF board, either R41 (15K 1/2 watt) has changed values or VR1 is bad. Clean VR1 and readjust as stated in the 520 service manual. Did you perform the complete S meter adjustments in the 520 service manual or just adjust VR1?

30950. neutralizing 6146Bs in a TS-830S and chattering relay

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-22 10:43:14 UTC

Topic: 30950 Message: 30950

Greetings to all:
I just resubscribed to the group. My TS-830S still has a chattering relay and I don't even use the relay now. I switch to send. I have all of Ken's K4EAA info and photographs on the relay placement.I think W5RKL mentioned that there are three relays that Kenwood used to describe RL-1 and Bob Mansker mentions a metal can near the cooling fan, under which is a relay.I would like to know which relay probably causes the chatter. I will probably end up replacing both.
On the neutralization issue I will probably use the plastic tool that Ken sells and wear gloves to boot. I don't have a high impedance vtvm or rf probe but I would like suggestions on what to buy inexpensively. I don't think I will use the second receiver and dummy load scenario.Where on the web ca I get a decent used high 1-11 Megohm vtvm and a cheap rf probe to connect to it. Then I need to figure out where to put the probe while I adjust the capacitor. Any help will really be appreciated. I have never attempted anyrhing like this before.

The relays in the 830, like the other hybrids, is controlled by "3" sources.

1. SEND switch
2. PTT switch
3. VOX Relay Amplifier

IF the relay chatter occurs when keying the transmitter with the PTT button or SEND switch then you should look for an intermittent connection in the microphone's PTT circuit or a loose SEND switch connection.

The "SEND" switch and microphone "PTT" controls are wired in "parallel". That means when you press the microphone's PTT button, it's the same as flipping the SEND switch UP.

If the relay chatter occurs only when using VOX, you might check the VOX GAIN and VOX DELAY settings. If the VOX GAIN and VOX DELAY are not set properly then the relays will energize but not remain energized when the audio level falls below the VOX GAIN setting. This can happen rather quickly. The VOX GAIN control is used to control the audio level from the microphone to the VOX amplifier. IF the gain is set too low then the VOX amplifier will not produce an amplified audio signal to the VOX Relay control circuits, hence VOX won't work. Adjusting the VOX gain control so the relays energize when speaking in a normal voice level 1 to 2 inches from the microphone, should result in the relay energizing. Once this is achieved, adjust the VOX DELAY control so the relays remain energized for about a second or 2 between words.

I recommend cleaning the VOX GAIN and VOX DELAY controls with DeoXit F5 pot cleaner and lubricant then test for proper operation.

I also recommend checking the PTT and SEND switch wiring for an intermittent connection. Make sure the microphone plug is fully seated into the microphone socket and the microphone plug ring is tight. Do not over tighten the microphone plug.

Also, check the microphone plug and wiring itself to ensure the problem is not a loose/bad PTT connection in the microphone plug.

You don't need to spend a lot of money on a VTVM. Any vintage Heathkit, Knightkit, or Eico tube VTVM will work fine. Most of these VTVMs are selling for $50 or less. Even if the VTVM does not come with a probe, you can build the probe yourself for less than $2. The schematics can be found on the Internet which show the probes circuit which is simple.

As for an RF probe, you can build one yourself for less than $10. I built one for less than $2. I used a small diameter short length of PVC pipe, short length of RG-174 coax cable, a 1N4007 diode and a .001ufd 500VDC disc capacitor. The link below will show you how to build one:

Hey guys, I am new here and looking for some help. I have a ts-520 that has been setting for some time. Last time it transmitted was probably about 13 yrs ago and that was just to make sure it worked. Aside from checking the tubes (I guess that would be a good idea). What else should I check out before running it very much? I have powered it up and it seems to RX ok, the s-meter seems to be a little weak, not much if any deflection on signals from stations that would show more on other rigs. Thanks in advance for any help.

Thanks & 73,
Mike KF4PHW

Hi Mike,

Sitting for 13 years is a long time.

The first thing I would do is to clean all of the wafer switches, including the wafer switches inside the final amplifier enclosure using DeoXit D5. Clean the pots with DeoXit F5 pot cleaner and lubricant. After cleaning the switches, use generous amounts of canned air, available at Walmart, to remove any cleaner residue. Read and adhere to the warnings/cautions on the cleaner's can. Contact cleaner, whether D5 or F5, is flammable. You van buy the non-flammable version if you so desire. However, don't forget to follow all of the warnings/cautions regardless of which one you buy and use. Apply just enough to the contacts to do the job. Rotate the switches throughout their travel in both directions a few times then use canned air to remove any/all cleaner residue.

It's quite possible the filter capacitors may be old and dried out. Voltage sagging is a clear indication the capacitors need replacing.

The final tubes may have accumulated a lot of gas over the 13 years. Don't rely on them to be good. I recommend replacing them. You may get lucky and not have to replace them but if one or both have an accumulation of gas at the base of the tube sooner or later the tube can, and most likely will, arc. You're best bet is to replace them then neutralize the final amplifier.

As for replacing ALL of the electrolytic capacitors simply because the 520 has been sitting for 13 years, no I would worry about that. The HV and LV filter capacitors, if found to be weak or have high internal leakage current, you might consider replacing them. Whether you replace the electrolytic capacitors or not is entirely up to you.

Topic: 30929 Message: 30954

Take openion from W5RKL first- this is very very important.

It is worth to go to Ken's kenwood repair site (Call sign of Ken is K4EAA)- where he explains in detail how to open the cover plate of VFO- (you can go to google and type kenwood hybrid repair and you will reach the Ken's web site for repairs) follow the instructions,

Let the rig sit idle for couple of hours so that all the capacitors get discharged. After 4 to 5 hours without any power line connection to the rig- earth the remaining charge using a very good insulated earthing tool. Remove the top cover of the rig. You can see the VFO Aluminium Box which houses a variable capacitor having aluminum plates

Open the cover plate of Variable capacitor Box (using a small screwdriver which is bent to 90 degrees so that it can reach to the cover plate screw)- spray some contact cleaner on the end bearings move the VFO from 0 to 600 five to six times- close the plate - wait for some time for contact cleaner to evaporate- and power up the rig-

While opening the cover plate you should be utmost careful (1) Not to touch the plates of variable capacitor. (2) Not to allow the screw (very small size) of the cover plate to fall in to the radio -then it will be difficult to retrieve it and it will short other circuits- and (3) open only one screw so that you can rotate the cover plate to peep in to the magic Variable capacitor enclosure.(4) No over sparying of contact cleaner please.

Best of Luck
Kshitij

Subject: [TS-520_820_530_830] TS-520 VFO (internal)

Hi and tnx for reading , i am currently having a problen with my ts-520 on every band 10-80 on the vfo from 350 to 450 i am getting dead spots where i have no transmit or recieve --dead silence and it is only in that spot on all bands any help would be nice so i can save the rig from hitting the bottom of the dumpster as this is very frustraiting when tuning to see what is there. any where else on the dial tune and load is great just in that area outlined is where the problem is.

Hi Mike,
Toward the end of your e-mail you mention building an RF probe to suit a VTVM. You give a reference to N5ESE's web instructions, where he shows a cct using a germanium 1N34 (or 34a), but you mention using a 1N4007.

Now I have a very nasty habit of "cross-linking" two items in my mind. So I MEAN 1N34a DIODE (or perhaps 1N4148 DIODE, or OA91 diode) and I think DIODE, and bingo - out of my mouth comes 1N4007, which is (of course) a different diode, and certainly not the one I intended. Perhaps you had in mind the 1N34 germanium diode mentioned on the web-site?

Different topic: If I use a 1N4148 silicon diode, (not the 1N34a, as per N5ESE) how much will this affect sensitivity? 700 vs 200 (as a ratio) ie 3 1/2 times less sensitive? Anyway, you suggestion to make an RF probe for my (old) HP VTVM I bought for $20 is excellent, and I'm going to do it! It's possible to do a great deal with basic test gear, intelligently used. Thanks for your reply!

The relays in the 830, like the other hybrids, is controlled by "3" sources.
1. SEND switch
2. PTT switch
3. VOX Relay Amplifier
IF the relay chatter occurs when keying the transmitter with the PTT button or SEND switch then you should look for an intermittent connection in the microphone's PTT circuit or a loose SEND switch connection.
The "SEND" switch and microphone "PTT" controls are wired in "parallel". That means when you press the microphone's PTT button, it's the same as flipping the SEND switch UP.
If the relay chatter occurs only when using VOX, you might check the VOX GAIN and VOX DELAY settings. If the VOX GAIN and VOX DELAY are not set properly then the relays will energize but not remain energized when the audio level falls below the VOX GAIN setting. This can happen rather quickly. The VOX GAIN control is used to control the audio level from the microphone to the VOX

amplifier. IF the gain is set too low then the VOX amplifier will not produce an amplified audio signal to the VOX Relay control circuits, hence VOX won't work. Adjusting the VOX gain control so the relays energize when speaking in a normal voice level 1 to 2 inches from the microphone, should result in the relay energizing. Once this is achieved, adjust the VOX DELAY control so the relays remain energized for about a second or 2 between words.
I recommend cleaning the VOX GAIN and VOX DELAY controls with DeoXit F5 pot cleaner and lubricant then test for proper operation.
I also recommend checking the PTT and SEND switch wiring for an intermittent connection. Make sure the microphone plug is fully seated into the microphone socket and the microphone plug ring is tight. Do not over tighten the microphone plug.
Also, check the microphone plug and wiring itself to ensure the problem is not a loose/bad PTT connection in the microphone plug.
You don't need to spend a lot of money on a VTVM. Any vintage Heathkit, Knightkit, or Eico tube VTVM will work fine. Most of these VTVMs are selling for $50 or less. Even if the VTVM does not come with a probe, you can build the probe yourself for less than $2. The schematics can be found on the Internet which show the probes circuit which is simple.
As for an RF probe, you can build one yourself for less than $10. I built one for less than $2. I used a small diameter short length of PVC pipe, short length of RG-174 coax cable, a 1N4007 diode and a .001ufd 500VDC disc capacitor. The link below will show you how to build one:

30956. TS520S MOD TO IMPROVE FLOOR NOISE LEVEL

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-22 22:04:19 UTC
From: jeffrey lord
Topic: 30956 Message: 30956

A Life member of our club from another State called in the other week, when I mentioned That I owned a T520S, he suggested that I change a component in the set , and it would improve the noise cancalling ability of the set.

However he rattled off the component numbers so fast that I could not remember them , and has now returned interstate.

With noise levels on 80m here sometimes registaring 20+ , i would like to look at the MOD.

So does anyone know the MOD that he was referring to?? and does it work and how well???

Jeff

Mike:
Thanks a lot. That was a very informative post about the issue about being wired in parallel and the importance of the VOX Delay and VOX gain controls. Since I have never operated SSB, strictly cw with the TS-830S, can you tell me how much of this info is relevant for cw? I have downloaded these posts and will be taking them to my Thai repairman and try to explain what areas to work on. Once again, thanks a lot for the really thorough post.

Subject: [TS-520_820_530_830] Re: neutralizing 6146Bs in a TS-830S and chattering relay

The relays in the 830, like the other hybrids, is controlled by "3" sources.

1. SEND switch

2. PTT switch

3. VOX Relay Amplifier

IF the relay chatter occurs when keying the transmitter with the PTT button or SEND switch then you should look for an intermittent connection in the microphone's PTT circuit or a loose SEND switch connection.

The "SEND" switch and microphone "PTT" controls are wired in "parallel". That means when you press the microphone's PTT button, it's the same as flipping the SEND switch UP.

If the relay chatter occurs only when using VOX, you might check the VOX GAIN and VOX DELAY settings. If the VOX GAIN and VOX DELAY are not set properly then the relays will energize but not remain energized when the audio level falls below the VOX GAIN setting. This can happen rather quickly. The VOX GAIN control is used to control the audio level from the microphone to the VOX amplifier. IF the gain is set too low then the VOX amplifier will not produce an amplified audio signal to the VOX Relay control circuits, hence VOX won't work. Adjusting the VOX gain control so the relays energize when speaking in a normal voice level 1 to 2 inches from the microphone, should result in the relay energizing. Once this is achieved, adjust the VOX DELAY control so the relays remain energized for about a second or 2 between words.

I recommend cleaning the VOX GAIN and VOX DELAY controls with DeoXit F5 pot cleaner and lubricant then test for proper operation.

I also recommend checking the PTT and SEND switch wiring for an intermittent connection. Make sure the microphone plug is fully seated into the microphone socket and the microphone plug ring is tight. Do not over tighten the microphone plug.

Also, check the microphone plug and wiring itself to ensure the problem is not a loose/bad PTT connection in the microphone plug.

You don't need to spend a lot of money on a VTVM. Any vintage Heathkit, Knightkit, or Eico tube VTVM will work fine. Most of these VTVMs are selling for $50 or less. Even if the VTVM does not come with a probe, you can build the probe yourself for less than $2. The schematics can be found on the Internet which show the probes circuit which is simple.

As for an RF probe, you can build one yourself for less than $10. I built one for less than $2. I used a small diameter short length of PVC pipe, short length of RG-174 coax cable, a 1N4007 diode and a .001ufd 500VDC disc capacitor. The link below will show you how to build one:

30959. TS-820 IF Unit 3.3vdc Voltage Problems

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-23 01:13:32 UTC
From: ae5uu
Topic: 30959 Message: 30959

The voltage problems with 3.3vdc bias in the IF Unit of my TS-820 continue. My 3.3vdc bias is 3.3vdc except when IF1 on the IF Unit is plugged in; then it is 6.2vdc, the problem that persists despite my best efforts.

Today I reinspected all the foil runs and found everything to be well. I have voltage measurement as follows:

Q-15

Base +7.5vdc (spec is +6.2vdc)
Collector +9.0vdc (spec is +9.0vdc)
Emitter +8.29vdc spec is +5.6vdc)

The Base and Emitter numbers are higher than specification.

Q-16

Base -5.3vdc (spec is -3.0vdc)
Collector +6.0vdc (spec is 0.0vdc)
Emitter -5.88 (spec is -6.0vdc)

The Base voltage is much too negative, the Collector voltage is positive instead of zero.

The problem does not prevent the radio from receiving well and transmitting a strong clear signal. However tuneup is challenging because I get no ALC reading when adjusting the Drive control in the TUN mode. Neither do I get any reduction in audio level nor increase in meter reading when the RF Gain control is rotated CCW.

All other voltages in the radio are correct with the exception of Q-5 on the RF Unit.

Q-5

Base Receive -96vdc (spec is -97vdc)
Transmit -51vdc (spec is -51vdc)

Collector Receive +5.06vdc (spec is 2.8vdc)
Transmit +9.04vdc (spec is 2.8vdc)

Emitter Receiver -96vdc (spec is -98vdc)
Transmit -51vdc (spec is -51vdc)

The Collector voltages are way off, perhaps also contributing to my ALC problem.

It has been suggested that I try removing D-20 on the IF Unit and then checking the 3.3vdc; there was no effect.

Any suggestions would be appreciated. Thank you.

73,

Russell
AE5UU

30960. Re: neutralizing 6146Bs in a TS-830S and chattering relay

From: w5rkl
Topic: 30950 Message: 30960

Hello Richard,

VOX is used in CW for "CW Break-in". While the VOX GAIN control isn't used for CW Break-in, the VOX DELAY control is.

With the 830 in CW and VOX turned ON, the 830 connected to a dummy load, send a series of DITS and DAHS. At the same time adjust the VOX DELAY until the transmitter remains keyed for a few seconds between the DITs and DAHs. When you stop sending CW, with the VOX DELAY set properly, the 830 should remain keyed for a few seconds then return to receive.

This is covered in the 830 operator's manual in the CW section.

>
>
>
> If the relay chatter occurs only when using VOX, you might check the VOX GAIN and VOX DELAY settings. If the VOX GAIN and VOX DELAY are not set properly then the relays will energize but not remain energized when the audio level falls below the VOX GAIN setting. This can happen rather quickly. The VOX GAIN control is used to control the audio level from the microphone to the VOX amplifier. IF the gain is set too low then the VOX amplifier will not produce an amplified audio signal to the VOX Relay control circuits, hence VOX won't work. Adjusting the VOX gain control so the relays energize when speaking in a normal voice level 1 to 2 inches from the microphone, should result in the relay energizing. Once this is achieved, adjust the VOX DELAY control so the relays remain energized for about a second or 2 between words.

Jef, I'll bet the member of your club is talking about "Pin diode mods". Don't waste you time and money, it's not worth it. If this is the mod you are referring to and that member said he "heard" a marked improvement in the receiver's noise floor, ask him how he determined that "marked improvement". What steps did he take to determine the Pin diode mod actually lowered the noise floor in his equipment.

If the noise being referred to is "external", meaning not in the equipment itself, then a mod to the transceiver will not eliminate that type of noise. Not all noise will be reduce or eliminated by a transceiver/receiver's noise limiter.

If the noise is external, possibly caused by power and telephone lines, then I recommend taking the time to read up on noise problems. There is a lot of information on the ARRL Website that discusses noises and their sources, what steps you can take, and how to handle eliminating these types of noise. The noise is not going away on it's own, you have to do some research and take steps to reduce and/or eliminate noise.

Jeff:

I am aware that there is a mod for the TS-820 that is designed to reduce the noise generated in the audio stages after the detector, thought to be due to excessive treble response in the receive audio stages.

The mod is described in an article on Mods.DK and simply consists of soldering a 0.1 uf capacitor across the AF Gain Control.

I have not tried the mod on my TS-820S and I have no idea whether it is applicable to the TS-520 but this may be what your friend is talking about. And at the worst I don't see how it could do any harm. In any case I find my TS-520 to be much less noisy than my TS-820S, but that may just be due to an actual difference in receive sensitivies between the two rigs.

Also, the Kenwood service bulletin on the TS-820 says that excessive noise can be caused by the failure of a tantalum capacitor in the PD section of the VCO/PD module. I tried replacing that cap with a ceramic bead cap of the same value in a spare VCO/PD module but got frequency instability as a result. I don't think this is applicable in any way to the TS-520.

Topic: 30964 Message: 30964

I have been able to save a TS 520S from the dumpster and I am working through many small problems and one big one I don't understand.

Receive and transmit is very good on all bands except 75 meters. The receiver on dial marker 0 should be 3500 kcs. Well this one is receiving 500 kc high. It starts to receive on about 3977 and goes up 500 kc from there. I can hear the Navy Mars Nets on 4012 USB and of course the MOX on 4006 very load. Remember the dial says approx 3520 or so. Just above the 0 indicator on the dial. Some one had a diddle stick in this thing . Can anyone start me in the right direction?

Hi Dennis,

Try measuring the frequencies at the VFO, CAR and particularly HET sockets on the back panel. With reference to the service manual, on 80m the HET frequency should be very close to 12.395MHz. The mixing scheme for the TS520 is RX frequency = HET - (CAR + VFO) and for 80m is 12.395MHz - (3.395MHz + 5.500MHz) If they all measure correctly then it's possible that someone has been in there and fiddled with the radio. A coil pack adjustment should bring everything back in line. If however, the HET signal is 500kHz high then it is very likely that someone has replaced the 80m crystal on the coil board. Test in TUN to see if the radio also transmits 500kHz high. If it does transmit 500kHz high then start by looking at crystal X2 on the coil board.

Check the 80 meter RF Unit HET OSC xtal. More than likely a previous owner has changed this xtal from 12.395Mhz to 12.795Mhz. Since you said the bottom of the 80 meter starts at 3.9Mhz then the HET OSC crystal will be 12.795Mhz instead of 12.395Mhz.

Replacement xtals can be obtained from International Crystals in Oklahoma City, OK for about $22 plus USPS shipping. See the link below for further details. Give them a call, they have an 800 toll free number.

http://www.icmfg.com/hamradio-manufacturers.html

You will have to adjust the COIL PACK again once you replace the wrong HET OSC crystal with the correct 12.395Mhz xtal. Perform the COIL PACK adjustment as stated in the 520 service manual. Don't simply adjust the 80 meter coil because there is a require sequence for the adjustment. Again, see the 520 service manual for details on the adjustments.

The CAR and VFO frequencies have nothing to do with the problem Dennis is experiencing.

Since the other bands are working fine, the only thing Dennis needs to check is the 80 meter RF Unit HET OSC xtal. It appears, based on comments from Dennis, it has been changed from 12.395Mhz to 12.795Mhz.

That's a great cake! It shows your mother knows how much the hobby means to you. I only wish my mom had lived to see me get my license last year (she passed away 3.5 years ago). She has encouraged me as a teen to get mine, but I can't do code, so now at 44 I've been licensed just over a year.

again, great pic:)

Hello Everyone,
I have owned my Ts-520 for a couple of months now.I have a tech license so I listen alot and have tried to transmit on 10 meters a few times with no response.I dont know for sure if it even works.I have a antenna tuner that I leave in bypass mode so I can read the forward power,swr,etc.. I have been told I dont need the tuner with this type of radio so I go through the tune up procedure and transmit without the tuner.I have to try to teach myself and so far Im not sure Im doing right.Do I need the tuner?If so what is the proper way to use the tuner with this radio?When I flip the switch to send in cw mode I see the foward and reflected power on the tuners meter but not when I transmit in ssb ?Are there some tests I can do to insure the radio transmits ok ?Any help would be appreciated.
Thank You

Jason,

I have a TS520S , you do need a tuner with this radio(TS520}.

You must tune the radio into a dummy load capable of 100Watts load at 50Ohms.
you can then tune the antenna with the TUNER with the Radio MODE SWITCH set to TUNE.

If the Antenna is too far out it may or may not harm the radio but you your RF output through the ANtenna will be greatly reduced, your 100Watts could end up as 10 or 15.

The TS520 at 10mt generally puts out about 90 Watts , at least all the owners I have spoken to have told me.

Hi Jeff and Jason,

I disagree, a tuner is not always required.

I agree a 50 ohm dummy load should be used to tune the 520 up into. However, I believe a 100 watt 50 ohm dummy load has too lower of a power rating to safely use it with the 520 regardless of the HF frequency. A 300 watt 50 ohm dummy load provides a much better margin of safety than a 100 watt 50 ohm dummy load. Always consider a margin of safety when selecting a 50 ohm dummy load.

Jason, you didn't say what type of antenna you are using on 10 meters nor did you say what the SWR is on that antenna. Before answering your question, you need to provide answers to those 2 questions. Follow the tuner's instruction when setting the FWD and SWR meter settings. Most all tuners will display the FWR power and reflected power (SWR) without going through the tuner (bypass mode).

Dennis,

International Crystals in Oklahoma City, OK, can provide you with the 12.395Mhz crystal you need. Their price for a 12.395Mhz crystal for your 520 is around $22 plus a few dollars USPS shipping. Give them a call.

http://www.icmfg.com/hamradio-manufacturers.html

I use them for all my crystal needs and have never receive a bad or off frequency crystal. All you need to do is tell them the make, model, frequency and type of crystal you need. I ordered two 40 meter heterodyne oscillator crystals, at separate times, for my Drake T4XB transmitter and my Drake R4C receiver and all I needed to tell them was the frequency and what the crystal was used for. They knew the rest. They are very easy to deal with, very friendly, and they take all major credit cards.

While you can buy a replacement 12.395Mhz crystal on eBay, I wouldn't trust a use crystal but that's me. Besides, $22 plus a few dollars USPS shipping cost quite often is cheaper than eBay prices plus you get a guarantee with International Crystals, something you quite often do not get on eBay.

I'm with you John. Back in the 1960's a mentor of mine stated many times (If you can dip the plate,go with it). He was right on. A tube rig can be very forgiving when it comes to SWR. Solid state not so much.

What type of tuner do you have? You should locate a manual for it and learn how to use it. As suggested, get a dummy load and transmit into the dummy load to test your RF output and tuning technique. Read your TS 520 manual and understand how to tune the rig. After you've got the rig tuned into a dummy load, reduce the power output and use your tuner to achieve a low SWR using your antenna. You can increase your RF output once your antenna is properly matched. Changing your operating frequency too far will require a touch-up in both the TS-520 and the antenna tuner. In SSB you should see relative power output when you speak or whistle into the microphone.

I have seen this same question asked on this forum so many times,that I really have to wonder WHY SSB theory is NOT TAUGHT in license classes.

EVERYONE OUGHT TO KNOW that an SSB transmitter does NOT put out any, or at least a very small amount of RF UNLESS the audio stages are modulated with a voice or tone ! ! !

That is one of the MOST BASIC PRINCIPLES of SSB transmission, and it seems to be TOTALLY OVERLOOKED !

The amount of power your radio will put out in the CW mode with the key closed, is the SAME AMOUNT of power that it will put out on voice peaks when properly modulated.

But the important difference is that the human voice has approximately a 30% average to peak ratio, so when speaking into a 100 watt radio with a normal voice, you should see only around 30 watts registering on your meters, simply due to the fact that they respond only to the AVERAGE POWER, and NOT to the PEAK POWER.

PLEASE, try to understand this. Trying to squeeze more power out in SSB only results in more distortion, spurious products and a generally poor sounding transmission.

sing a tuner will not make an unsuitable antenna work on a band it's not designed for. for example; trying to use a two meter antenna work on ten meters is futile. Maybe you can tune the SWR down , you still will get hardly any signal out on the air.
It's not magic, it's Physics.

Hey Guys,

I just wanted to throw my 2 cents in for what it's worth. I've been using a plain jane TS-520 since October of last year. It's the one that Mike W5RKL helped me troubleshoot a while back. I use a tuner with mine as I only have 1 antenna that needs to be "tuned" to all bands. If you have a perfect match with the antenna you are using for 10M then by all means consider yourself lucky and don't touch it. I cut my antenna for 40 meters and it is a perfect match there, but it varies through out the bands so it is better to be safe than sorry. Hence I keep the tuner inline.

I can get 120 Watts all day long out of this 520.

The way I tune it is in the tune setting as previously mentioned above. While the output power is reduced, I turn the knobs on the tuner until the swr is at minimum. Sure wish I had an autotuner right about now though!

Then I complete the tune up procedure that is outlined in the manual and voila! Just because you see 120 W in CW mode, doesn't mean you will see it while chatting on SSB. The CW tone is 100% duty cycle while your voice generally speaking is not even though my xyl's might be. Digital modes work similar to CW and are also 100% duty cycle for the most part which is why it is important to keep your SWR at a minimum. In my opinion, any reflected power is just bad news..

Does anyone think many technical questions can be answered "YES" or "NO".??
Some explanation of WHY should be offered or there is no point in answering..
Do I need a tuner? Answer yes or no only ?? Nonsense !

An antenna tuner is helpful when you don't have a perfect antenna match to your transmitter. It certainly isn't necessary... but, it can be very helpful especially on the lower bands where getting a decent match across the entire band is often difficult. An antenna tuner doesn't cure a mismatch or fix a poor antenna, it just makes the transmitter happy. The nice thing about a tuner is the convenience of having a built in SWR/Watt meter. However a dummy load is essential for good operating practice in my opinion.

Dave, that's not fair,

Jim is right in every way.
If you have a licence, there should be at least a understanding of the basic principles of SSB, antenna's and the polarity of a diode.
Nowadays it seems the norm to do nothing to find out for yourself, but ask in a forum as this. There is no problem with that, but most questions are endless repeats that can easely found an answer for by looking in the archives of the forum.

Asking the same simple things again and again can be very tiring for the good-willing experienced helpers like Jim on this and other forums.
Everyone has to start somewhere, and we are ready to help, but you have to understand some of the basics, that can be found in every ARRL handbook that cost maybe 3 dollars in a secondhand shop.

Ducking and running :0)

I missed the "lecture" I guess.
But I really think some of the things ask in the past have either
been ask before -or- was a question on the FCC test. In either case a
fast and dirty search would show it.

I know that I do get a bit on the nasty side but I really think is because
of putting a lifetime into the radio and TV business as well as a number as
a 2 way radio tech at a radio shop.

Mark Twain said "that only stupid question was the one never asked" ?

No Dave, it is NOT a lecture, AT ALL. Not unless you happen to be a teacher that doesn't teach that fundamental aspect about SSB radio!

I am just asking a question like anybody else here on this forum. Since SSB theory is SO FUNDAMENTAL to ham radio operation, WHY does the question keep popping up here and on other forums? WHY isn't more emphasis placed on the TECHNICAL BASICS of ham radio?

If you have a guilty complex, perhaps it is trying to tell you something.

Over on QRZ.COM, the question comes up, almost weekly, and one of us is only too eager to set the record straight.

Don't go lecturing ME about supplying lectures rather than answers. I believe my post count over there is around 15000, and most of them are related to answering questions.

I have seen this same question asked on this forum so many times,that I
really have to wonder WHY SSB theory is NOT TAUGHT in license classes.

EVERYONE OUGHT TO KNOW that an SSB transmitter does NOT put out any, or at
least a very small amount of RF UNLESS the audio stages are modulated with a
voice or tone ! ! !

That is one of the MOST BASIC PRINCIPLES of SSB transmission, and it seems
to be TOTALLY OVERLOOKED !

The amount of power your radio will put out in the CW mode with the key
closed, is the SAME AMOUNT of power that it will put out on voice peaks when
properly modulated.

But the important difference is that the human voice has approximately a 30% average to peak ratio, so when speaking into a 100 watt radio with a normal voice, you should see only around 30 watts registering on your meters, simply due to the fact that they respond only to the AVERAGE POWER, and NOT to the PEAK POWER.

PLEASE, try to understand this. Trying to squeeze more power out in SSB only results in more distortion, spurious products and a generally poor sounding transmission.

Dave, that's not fair,

Jim is right in every way.
If you have a licence, there should be at least a understanding of the basic principles of SSB, antenna's and the polarity of a diode.
Nowadays it seems the norm to do nothing to find out for yourself, but ask in a forum as this. There is no problem with that, but most questions are endless repeats that can easely found an answer for by looking in the archives of the forum.

Asking the same simple things again and again can be very tiring for the good-willing experienced helpers like Jim on this and other forums.
Everyone has to start somewhere, and we are ready to help, but you have to understand some of the basics, that can be found in every ARRL handbook that cost maybe 3 dollars in a secondhand shop.

Ducking and running :0)

Just in case anyone misunderstood my comment, I was answering
Jim S's statement why folks had to keep asking questions in regard
to SSB.
I joined 'cause I'm thinking I may be in the market for an '820. The
way Jim S. stated his views, it sounded like he doesn't think anyone
should have to ask certain questions.
I've been a ham probably as long as many have (50 years this month)
but I still have questions from time to time.

Gotta agree with Joe 100%
As a matter of fact, the requirement to take the test for your ticket should be
A) 2 pieces of ID.
B) A Dummy Load.
C) $12.00 for your exam fee.

On further consideration!
B) A Dummy Load and a copy of ARRL Operating Manual.

An antenna tuner is helpful when you don't have a perfect antenna match to
your transmitter. It certainly isn't necessary... but, it can be very
helpful especially on the lower bands where getting a decent match across
the entire band is often difficult. An antenna tuner doesn't cure a mismatch
or fix a poor antenna, it just makes the transmitter happy. The nice thing
about a tuner is the convenience of having a built in SWR/Watt meter.
However a dummy load is essential for good operating practice in my opinion.

In support of Jim.
This very same subject matter is being discussed on the 480 Forum at this moment.

Is it that some of us are too Lazy read the BASIC?

No Dave, it is NOT a lecture, AT ALL. Not unless you happen to be a teacher that doesn't teach that fundamental aspect about SSB radio!

I am just asking a question like anybody else here on this forum. Since SSB theory is SO FUNDAMENTAL to ham radio operation, WHY does the question keep popping up here and on other forums? WHY isn't more emphasis placed on the TECHNICAL BASICS of ham radio?

If you have a guilty complex, perhaps it is trying to tell you something.

Over on QRZ.COM, the question comes up, almost weekly, and one of us is only too eager to set the record straight.

Don't go lecturing ME about supplying lectures rather than answers. I believe my post count over there is around 15000, and most of them are related to answering questions.

I have seen this same question asked on this forum so many times,that I really have to wonder WHY SSB theory is NOT TAUGHT in license classes.

EVERYONE OUGHT TO KNOW that an SSB transmitter does NOT put out any, or at least a very small amount of RF UNLESS the audio stages are modulated with a voice or tone ! ! !

That is one of the MOST BASIC PRINCIPLES of SSB transmission, and it seems to be TOTALLY OVERLOOKED !

The amount of power your radio will put out in the CW mode with the key closed, is the SAME AMOUNT of power that it will put out on voice peaks when properly modulated.

But the important difference is that the human voice has approximately a 30% average to peak ratio, so when speaking into a 100 watt radio with a normal voice, you should see only around 30 watts registering on your meters, simply due to the fact that they respond only to the AVERAGE POWER, and NOT to the PEAK POWER.

PLEASE, try to understand this. Trying to squeeze more power out in SSB only results in more distortion, spurious products and a generally poor sounding transmission.

I agree with STEVE , even though with some ANTENNAS a tuner is excess baggage, it is kinder to the tubes in the set, NO need to place excessive load via antenna mismatch if it can be avoided.

My set up ihas been checked by several of my clubs FULL CALL HAMS , and all agree that the TUNER is better in line than out.

WIth respect to the dummy load, mine is a 40Watt home brew. it will tolorate 100watts, for 30 seconds without heating up too much , a 100watt will be more than enough, especially if only 100 - 120 watts output, and the key is not held down for more than 30 seconds.

What type of Antenna do you have, ?, I do use a doublet with open wire feeder, and the tuner is necessary.

Subject: Re: [TS-520_820_530_830] Need Help with kenwood ts-520

Hey Guys,

I just wanted to throw my 2 cents in for what it's worth. I've been using a plain jane TS-520 since October of last year. It's the one that Mike W5RKL helped me troubleshoot a while back. I use a tuner with mine as I only have 1 antenna that needs to be "tuned" to all bands. If you have a perfect match with the antenna you are using for 10M then by all means consider yourself lucky and don't touch it. I cut my antenna for 40 meters and it is a perfect match there, but it varies through out the bands so it is better to be safe than sorry. Hence I keep the tuner inline.

I can get 120 Watts all day long out of this 520.

The way I tune it is in the tune setting as previously mentioned above. While the output power is reduced, I turn the knobs on the tuner until the swr is at minimum. Sure wish I had an autotuner right about now though!

Then I complete the tune up procedure that is outlined in the manual and voila! Just because you see 120 W in CW mode, doesn't mean you will see it while chatting on SSB. The CW tone is 100% duty cycle while your voice generally speaking is not even though my xyl's might be. Digital modes work similar to CW and are also 100% duty cycle for the most part which is why it is important to keep your SWR at a minimum. In my opinion, any reflected power is just bad news..

30999. possible to align radio so badly that you get NO ALC movement?

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-25 23:09:45 UTC
From: kd0fds
Topic: 30999 Message: 30999

I adopted a tech special TS-820s and I've been having a great time learning about, from, and with the radio.

I've never really used HF, so I don't have much to compare real world performance to. This makes it hard for me to know if things are "right" or not sometimes, but I'm expanding my experiences with each effort on the radio and the assistance of these forums.
I've read literally hundreds of posts on this forum and found an overload of great information.

Last weekend I "unrepaired" my radio.

Before I started an alignment, I was able to tune up into the dummy load just fine. I was able to receive some stations mostly from the western coast on 20 and 40 meters. Heck, I even had the digital display working correctly for about 30 minutes!

I was working on an alignment, starting with a 25k generator tuning comparing to WWV. I probably messed up right there. I went down the manual and everything seemed to be going well, I was making small adjustments to the tuning coils for peak S meter readings on receive with the tone generator on and the VFO tuned to a comfortably pitched tone. No. I've never actually done this before, but I guess it is like balancing dual (or triple) SU carbs on your Austin Healey, eh?

I got to the alignment of the DRIVE slugs. I used to get ALC meter movement when practicing tuning up the radio (into a 50 ohm dummy load), but now I don't get ALC meter movement and I don't seem to have any RF output either! Ack! What have I done?!

I have idle current, I have 800+ volts with the meter on HV. 3.3 and 9 volt adjusted correctly just fine. 3.3 was about 10% low at one point in my repair process, but it has been running at 3.3 for afew weeks now. The big cathode resistors measure out a little bit high, but probably still in spec.

Is it possible that I have tuned my radio so far out of whack that I can't get any output?! Way to go ME!

The good news is that I'm not wrecking a "good" radio here. I'm bringing one back into service and learning enough to keep it working in the future.

How about a friendly hand from the group to help me figure out what I just learned the hard way about my TS-820s?! Thanks, Stephen

John & all,

I have been gone out of town for awhile and have now read the e-mails regarding the "controversy." I started out as a Radioman in the USCG in the mid/late '70's. We very highly trained professionals ...but did not repair...etc. our equipment, that was a job for the ET(electronics technician(s)). I received my first license circa 1977(Novice)..code was not a problem...I graduated Radioman School with a "High Speed" rating of 24WPM receive..24WPM send..w/Vibroplex "BUG." Electronics has never been my strong suite...as I have a learning disability regarding math. This group has been, a GREAT HELP learning(re-learning) some pretty basic principals, and trouble shooting techniques. I have been able...with the help of the group to,... mitigate numerous problems...and actually FIX some stuff. I carried a NOVICE ticket until just a few years ago. I went to a local radio club... 1 month of self-study...and passed the TECH and then the GENERAL in one sitting. I was offered to sit for the EXTRA...but I had to get back to work. From what I remember from the prior exam manuals... when there were ...what...4-5 classes of "tickets".....these tests were pretty EASY...pretty much no "theory" just the "legal stuff." I do agree however that some of the current day operators are just that......operators. Just like modern day TV and such...just "turn em on." no need to really know how they work. I enjoy...the hobby...the people...but please remember...we are not all an electronic genius. I do agree also...that there are WAY TO MANY "operators" that think that turning up the "MIC GAIN" and/or running "full legal limit" when it's not really necessary is the "WAY TO GO." You know the "BIG GUNS!"..which is funny because the FCC rules clearly state..that you shall not use more power than is required to carry out the communication(s)(para-phrased). I have a very modest station...and old 820S & 830S and even older(until january..lost antenna in wind storm) Mini Products HQ-1 2 ele beam...and really never seemed to have significant problems working anything I could hear...even in a pile-up...maybe just took some time. So...in short...it's our fault...big government regulating or un-regulating...more bodies equals more $$$ and more "voices" even though those "voices" may not know what they are talking about...so...more than likely... I just hacked some people off...but thanks for reading this far....Mike(w5rkl) & Gordon(n6wk)...and Ken Kemski(k4eaa) thanks in helping us keepin' these old things hummin'!!!

31005. Another new guy with questions

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-26 01:03:57 UTC
From: kevin
Topic: 31005 Message: 31005

I have been a ham for less than two years. I started with a 520 because I thought it would be more challenging and fun to learn about the hobby from point of view that was not just plug and play. Others see it differently and more power to them.

One thing that people tend to forget is now intimidating this can all be in the beginning. We all want to be good operators and do not want to make operating errors especially on the air.

Another thing that gets lost on the experienced ham is that this is anew language. Because of that many old hands and many publications use language that they assume everyone knows. This is just simply not true. You may not even know what question to ask. True if you read enough you can usually pick it up from cross referencing many articles but maybe not. There is also a lot of conflicting information. Just ask 5 hams how to tune a Hybrid and an old Tube amp together.

I made the same SSB band mistake when I first started with this radio. I figured it out myself but only from trial and error. Then I felt stupid because the did in fact teach about SSB in class. Who hasn't made this type of error?

I am a bit taken back when someone asks a newbie kind of question and gets jumped on (many groups are WAY worse), but more impressed when 99.9% of the time people here take the time to give detailed explanations that a new ham understands. It helps someone like myself learn and hopefully I will be able to share with others in the future.

An Elmer is a person who teaches and nurtures the neophyte amateur radio operator.

From what I have seen, the vast majority of hams on this list just keep helping and helping to answer the questions. I am happy to see that.

The quality of the ham operators of the future will depend upon the day-to-day examples of the old timers of yesterday and today. I would encourage hams to be continue to be more like the true Elmer.

Many thanks to all who follow the path of the Elmer...and of a friend.

I just did a lot of work on my 830S including replacing the HV filter caps, screen and grid resistors, and doing a complete alignment. The owners manual states that the neutralization should be done on 10 meters. I did it 4 times, and every time when moving down to the lower bands I would have the rig run away and blow the 115V fuse.

I used a Tektronik 60 MHZ scope.

I then started the neutralization at lower bands, and finally finished by balancing the low point as viewed on the scope between 20 and 17 meters. The result was full power out on all bands from 160 to 10 meters, and huge drop in current to the finals. Also the maximum power occurred at the final dip point for the first time since I have owned this rig.

On the air signal checks have been positive too.

I guess the Kenwood manuals are not infallible.

To me using a hybrid radio,Kenwoods, it is like the first time that I got to drive my fathers 69 Chevelle. She may start a little cold in the mornings and she runs best after you let her run for 15 or 20 mins but you never forget the ride. Alas I digress, I have noticed a general consensus in some circles that are brow beating newer hams when a simple(to us) question is asked. Some will say I had to learn from a book, let them learn it that way. Where did the term Elmer come from? It is such a popular word in amateur radio circles. You can ask those hams that don't feel that we have a responsibility to help the newer hams to the hobby, but ask those same people who there Elmer was and they can tell you his name, where he lived and what kind of coffee that he drinks. I find that funny, I mean Elmer usually congers up thoughts of an older ham that showed you the ropes, but yet these same people tell you to look it up for yourself. Ironic isn't it. I believe wholeheartedly in the term pay it forward, and I think many others do to. Lets just hope that those curmudgeons don't ruin the whole crop.

Rick,

I mean no disrespect but your experience is a prime example where "memorizing questions and answers" by taking practice test over and over again does not teach you or anyone else who uses this method to pass the test, a darn thing!

When I give a response to a question, I typically include supporting statements so the person actually learns why certain steps are to be taken. I have also stated that operators should read the "Circuit Description" section of the manuals plus study the block diagrams. If they have any questions then they should come here and ask for an explanation. There are some who take it upon themselves to actually read and study this information but for the most part, many do not. If you want to learn you need to start learning the basic "first"! You can't learn advance subjects without having a thorough understanding of the basics "FIRST"!

I will be glad to help anyone who wants to learn. If you don't understand something, regardless of what it is, don't sit like a bump on a log, ask for help. Don't expect me or anyone else to take hold your hand and always GIVE YOU THE ANSWERS! You, as a student, have a responsibility to "STUDY" on your own. You will not learn a darn thing if the answer are always given to you because you are too lazy to study! This may seem harsh to some but learning is a "2 way street".

If any of your are interested in learning the basics, I recommend you buy and study the first 2 or 3 chapters in the 50s and 60s versions of the ARRL Handbook. If you can find it, buy and read the first 2 or 3 chapters in the "Basic Radio Course" by John T. Frye. If you think this information is "out dated" and you won't learn a thing by reading it, THINK AGAIN! Basic electronics does NOT go OUT OF DATE because it's the year 2011 and the information in the reference material provide above is dated 1950 or 1960!

Again, if you have any questions, ask for help either here or e-mail me. Don't expect to learn it over night, in a week or month. It takes a lot of studying, reading the chapters over and over again, and asking lots of questions before you will learn it.

Another way to pickup fundamentals of electronics is through the Cleveland Institute of Electronics, CIE using a correspondence course. I took the 'tube based' 1st class FCC license course back in 1969-1970 which was about $470 then.

Here's their URL: http://www.cie-wc.edu/

One thing I found was that they had a simplistic view of electronics, that made learning very fast. I learned mathematics/how to use a slide rule/calculator in four small books. I was amazing since I hated the subject of math in high school, this was SO easy. and the rest of the course went by almost too soon. And yes, I received my FCC license when there WAS such a thing.

The most amazing part was what/and the amount I learned in 1 year, vs what I learned in high school. NO comparison.

CIE is just one institution, there are several out their, google electronics correspondence courses.

31016. Re: Need Help with kenwood ts-520 - FAQ needed?

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-26 14:29:47 UTC
From: Bill
Topic: 30974 Message: 31016

Hi,

Some of the responses in this thread are disappointing with eruptions into flames.

Online searches and "archive' searches will now turn up the flames and those are not going to help anybody. It's happened to me, too. I try to search for any kind of information and find a long list of snide remarks that are not the least bit helpful. I finally ask a direct question on an appropriate list and I get told to try searching for the answer myself, usually in quite crude terms. Of course...that reply gets added to the pile, too.

I have also tried to search the archives of various lists and the archives don't seem to be organized very well for actually retrieving information. So lets be fair about that, too. If a question was asked last week maybe the subject line only says "help needed with 520". How is one to know "help with what part"?

I noticed immediately when I joined *THIS* list that the same questions get asked over and over and over again. That's a great sign the list should start building some FAQ pages. For those who don't know, "FAQ" means 'Frequently Asked Questions'. Oh yes...some new people will come along and overlook the FAQ files and ask anyway. They can then be referred to the FAQ pages instead of having to explain over and over and over again. Explaining over and over and over again can wear on ya AND each time you can slip new typos in there. FAQ pages can be refined and typos or mis-statements cleaned up over time. How can we lose?

About those antenna tuners. I like end fed wires on HF. That means one antenna does it all for me. At the root of it any antenna that couples your RF to the ether is a good antenna. Hams use a dipole for a specific band or maybe an array made of dipoles for a band or bands and those just happen to be near 50 ohms for hams who are using solid state radios or later model tube rigs with adjustable "pi" networks at the output. That station form works well and is easy to implement. End fed wires (and other antennas) are just not so simple. They can present a very wide range of impedances to a transmitter and more specifically to the output filter in that transmitter. Solid state rigs have typically fixed output filters and they are designed for 50 ohms. With anything other than 50 ohms you lose the filtering capability whether or not you lose your finals. Later tube rigs - like ours - with adjustable output filters can match into a somewhat wider range but they are *NOT* as robust as the networks built into transmitters in an earlier day. Your Kenwood Hybrid will be just fine with any dipole built for the band you are using it with and no tuner needed.

So to wrap this up...who wants to help build the FAQ files for this list (and perhaps other lists)? I'll help, too.

73,

Bill KU8H

Than you for letting me join the group. I am a 65 years old who has enjoyed SWL sense I was a boy, the book The Boy Electrician I read a number of times.

My aunt gave me an old 1939 floor model radio that had short wave frequencies on it and that got me hooked. I built a Science Fair Globe Patrol and listen to Hams all over the world with a long wire out my window, and I still have a Globe Patrol. In the 70's I purchased a Realistic DX 160, and still have it.

When I retired I decide to get my Ham ticket and to my surprise, no code and I had my technician license the next week, 4/8/2011 I expect to take my general exam 5/7/2011, wish me luck.

I have purchased a Kenwood TS-520S and a dummy load off ebay waiting for them to arrive, now I'm thinking on what kind of antenna I should use, maybe a G5RV used as an inverted V. Any thought on that would be appreciated also suggestions on a simple and inexpensive support for it.

No offence taken. It may just be a sign of the times, but the hams that encouraged me to take up the hobby also encouraged me to take the shortest route to the license. Being fully licensed, but incompetent none the less has always bothered me more than it has others and I am the one who has initiated remedial education for myself.

Monitoring such lists as this is a part of that education and I rarely post, but always learn. I learn from the disagreements and repetitions and sometimes from the disinformation and I appreciate the participation of all.

Thanks for the recommendation of a source for foundational information. I will try to secure one.

Rick

If any of your are interested in learning the basics, I recommend you buy and study the first 2 or 3 chapters in the 50s and 60s versions of the ARRL Handbook. If you can find it, buy and read the first 2 or 3 chapters in the "Basic Radio Course" by John T. Frye. If you think this information is "out dated" and you won't learn a thing by reading it, THINK AGAIN! Basic electronics does NOT go OUT OF DATE because it's the year 2011 and the

information in the reference material provide above is dated 1950 or 1960!

Again, if you have any questions, ask for help either here or e-mail me. Don't expect to learn it over night, in a week or month. It takes a lot of studying, reading the chapters over and over again, and asking lots of questions before you will learn it.

Hello Jim,

Welcome to the Kenwood group.

Since you are new to the hobby and new to the use of a Kenwood TS-520, may I recommend you read the 520 operator's manual thoroughly. If you have any questions about anything you have read, please ask them before you attempt to operate your 520.

Once you have a firm grasp/understanding of what's expected of you when you operate your 520, the operating experience will be much more enjoyable. Quite often new operators tend to jump into operating the equipment without taking the time to read over the operator's manual and ask question about sections they don't understand. This quite often results in frustrated operators who can easily loose interest.

As for what type of antenna you will need, since this is your first time, may I recommend a simple dipole for 40 meters. I say 40 meters because 40 meters is the ideal band for day and night time communications. During the day you can have contacts 500 miles and at night, long distances even DX stations in Europe. In very early morning hours, 4 or 5am, the South Pacific, New Zealand, Australia, and the Far East can be heard. Start simple first then once you have some experience you can upgrade to a more elaborate antenna (G5RV) which will require additional equipment, a tuner. But for now, keep it simple.

If you have a few tall trees far enough apart, about 67 feet for a 1/2 wave 40 meter dipole, you can string the dipole between the 2 trees. Put the dipole as high as possible and allow the feed line, typically 50 ohm coaxial cable, straight down and finally terminating at your operating position. You can also purchase a commercially made shortened dipole, one with coils called traps, that will allow you to use it if you don't have enough space in your back yard.

Attic antennas can be used but there will be some reduction in performance. Attic antennas also can cause RFI (Radio Frequency Interference) to such things as telephones, televisions, stereo surround sounds systems, as well as affecting some touch lamps. It also can contribute to RF distortion when operating sideband voice due to high RF fields if the station is located very close to the antenna itself.

Here are some links to amateur radio stores you might consider visiting while you are waiting for the arrival of your 520.

www.n6wk.com/kenwood/
(download the 520 operating manual(s) here).

http://www.aesham.com/
(online store that carries antennas, cables, transceivers, power supplies, etc)

http://w8ji.com/
(great technical information website. Good site for reading about antennas especially about baluns)

http://www.arrl.org/part-97-amateur-radio
(excellent source for FCC's part 97 Rules and Regulations pertaining to Amateur Radio operation in the United States)

And of course, here for questions about information you don't understand. Don't forget the "files" section here. There is a lot of valuable/information data that you can download and read, free of charge.

Van, I will echo what you said about Cleveland Institute of Electronics. Upon graduating from high school in 1958, I realized I needed additional education to be able to make a decent living. I had received a General Class ham ticket in my sophomore year. Those were the days when the General Class exam did not contain all multiple choice questions. You had to actually draw diagrams and write out answers for some of the questions. There were no “question pools” so you could never be sure what questions would be on the test or how they would be asked. However, I had a serious problem. I was very poor. I had raised and sold tomatoes and done simple radio and TV repair to get a Heathkit AT-1 transmitter and a used Hallicrafters S-40B receiver. My test equipment consisted of a cheap VOM and the tube tester at the local drug store. Going to college or trade school was out of the question. I lived in a rural area and scholarships, student loans, and grants were very scarce or nonexistent. I couldn’t even afford correspondence courses that included test equipment or radios. I signed up for two CIE courses: one to train for the Second Class Commercial ticket and later for the First Class. The lessons were well designed and easy to follow. I found them exciting and I couldn’t wait for the next book to arrive. I had taken all the math courses offered by my little high school so I already knew most of the math except for trig. The CIE course provided a sound education in trig, and I became very proficient with the slide rule. All in all I ended up with a good, solid education in electronics and passed the FCC exams with flying colors. My voice had matured when I was about thirteen so I sounded like I was about thirty. With a book from the library and an old Webcor tape recorder I had trained myself to be a decent announcer. With my First Class ticket in hand, I thought my troubles were over, but that was not to be. The local 250-watt AM broadcast station would not hire me because I had no connections and had not been popular in high school. There were no other electronics job possibilities in my hometown. I went to stay with a relative in Dayton while I looked for a job there. It was there I found the downside to correspondence schools. I had no hands-on experience. My diploma from CIE and experience in ham radio was not enough. It seems the people with FCC licenses that got jobs had worked their way up in the field. They had not received their license just out of high school. Even with my knowledge in radio and electronics, I had to settle for minimum wage jobs that had nothing to do with my chosen field. However all was not lost. I was fortunate enough to find an area that was hurting for guys like me. That was something new called computers. Of course CIE did not cover digital electronics, but I was able to take a course at a community college that filled in that gap. With my background from CIE I was off and running. I graduated from the University of Dayton, became a software engineer with an international corporation, taught computer science at a community college, and worked as the operations manager at an FM broadcast station. My diploma from CIE still hangs proudly on my wall.

Subject: Re: [TS-520_820_530_830] Re: The hams of the future

Another way to pickup fundamentals of electronics is through the Cleveland Institute of Electronics, CIE using a correspondence course. I took the 'tube based' 1st class FCC license course back in 1969-1970 which was about $470 then.

Here's their URL: http://www.cie-wc.edu/

One thing I found was that they had a simplistic view of electronics, that made learning very fast. I learned mathematics/how to use a slide rule/calculator in four small books. I was amazing since I hated the subject of math in high school, this was SO easy. and the rest of the course went by almost too soon. And yes, I received my FCC license when there WAS such a thing.

The most amazing part was what/and the amount I learned in 1 year, vs what I learned in high school. NO comparison.

CIE is just one institution, there are several out their, google electronics correspondence courses.

31022. Re: Need Help with kenwood ts-520 - FAQ needed?

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-26 16:25:35 UTC
From: w5rkl
Topic: 30974 Message: 31022

Hi Bill,

FAQs are good to have but whether Yahoo can support an FAQ file or not is another story. How would the FAQ file be searched? Is there enough storage space available through Yahoo without having to pay a monthly fee? If a monthly fee would be required for additional storage space, how much would the cost be for each member? Would that make the Yahoo Kenwood group require each member to pay a fee to join? If so with the economy the way it is today, how many members would be willing to pay that fee? I don't know the answers to those questions but maybe Gordon and Walt do.

If it is possible to create an FAQ file without any cost involved then I would be glad to contribute to an FAQ file.

>
> Hi,
>
> Some of the responses in this thread are disappointing with eruptions into flames.
>
> Online searches and "archive' searches will now turn up the flames and those are not going to help anybody. It's happened to me, too. I try to search for any kind of information and find a long list of snide remarks that are not the least bit helpful. I finally ask a direct question on an appropriate list and I get told to try searching for the answer myself, usually in quite crude terms. Of course...that reply gets added to the pile, too.
>
> I have also tried to search the archives of various lists and the archives don't seem to be organized very well for actually retrieving information. So lets be fair about that, too. If a question was asked last week maybe the subject line only says "help needed with 520". How is one to know "help with what part"?
>
> I noticed immediately when I joined *THIS* list that the same questions get asked over and over and over again. That's a great sign the list should start building some FAQ pages. For those who don't know, "FAQ" means 'Frequently Asked Questions'. Oh yes...some new people will come along and overlook the FAQ files and ask anyway. They can then be referred to the FAQ pages instead of having to explain over and over and over again. Explaining over and over and over again can wear on ya AND each time you can slip new typos in there. FAQ pages can be refined and typos or mis-statements cleaned up over time. How can we lose?
>
> About those antenna tuners. I like end fed wires on HF. That means one antenna does it all for me. At the root of it any antenna that couples your RF to the ether is a good antenna. Hams use a dipole for a specific band or maybe an array made of dipoles for a band

or bands and those just happen to be near 50 ohms for hams who are using solid state radios or later model tube rigs with adjustable "pi" networks at the output. That station form works well and is easy to implement. End fed wires (and other antennas) are just not so simple. They can present a very wide range of impedances to a transmitter and more specifically to the output filter in that transmitter. Solid state rigs have typically fixed output filters and they are designed for 50 ohms. With anything other than 50 ohms you lose the filtering capability whether or not you lose your finals. Later tube rigs - like ours - with adjustable output filters can match into a somewhat wider range but they are *NOT* as robust as the networks built into transmitters in an earlier day. Your Kenwood Hybrid will be just fine with any dipole built for the band you are using it with and no tuner needed.

> So to wrap this up...who wants to help build the FAQ files for this list (and perhaps other lists)? I'll help, too.

Hi Rick, yeah I'm on board with you on that too, couldn't agree more. Sad to say, I have a General that I feel I didn't really 'earn' the right to own, considering what a few of my elmers hams did in the past to get theirs. However, I'm making the best of my General now with the priciples I'd learned about good amateur radio practice and the like. I'm am one of those guilty of 'bashing' the General test, but at least I already had the practical values of amateur radio inculcated in me, along with the electronics knowledge as well. (Actually, the electronics theory was pretty easy for me since I was already a practitioner and hobbiest of it for many years.) So there's my input for what it's worth. Being the fact that the tests are fairly easy pickin's these days should not keep us from learning good values (and hopefully good electronic know-how as well). These user groups are exelent resources for such.

73,

Bob, KD5MHQ

I don’t know how many have noticed, the technician and general tests are fairly easy to pass if you just take the many practice exams over enough. I realized just after I “earned” my general that I didn’t really know jack ____ about the things in which I was supposed to be proficient. I have been asking questions ever since to find out what I would have known if I wasn’t such a good test-taker. Thank you to everyone who has not only answered my questions, but rewarded my desire to learn by not humiliating me when I asked a question.

73,

Rick KF7JFU

Stephen:

Anything is possible, especially when you are talking about using a diddle stick inside a radio. I bought a Tech Special TS-820S the year before last, ended up buying a number of spare subassemblies for it, and in the end found out that other than the usual burned out resistors in the power supply section the main thing it needed was adjustments. Other than the burned out resistors the only thing that needed replacement was the SSB filter, which did work Okay on USB but not on LSB.

First, I recommend that you use a better alignment procedure than the one in the original manual, which has some errors and omissions as well as it not quite being written in english. If you provide me with an e-mail address where I can send you a small PDF file you can use the procedure I employed. Unfortunately, I no longer know where it came from on the Internet so I can't direct you there.

Good Luck!

Robert

Don't ever let a radio intimidate you. Thats the way you learn. If one doesn't work, it for sure you can't hurt it. I own and maintain a repeater, its an education, but it has been trouble free for years now. Once you get things going your way you will feel good about it.

Thanks Glenn, opportunity for education is
everywhere, one just has to look for it.
It helps to have someone elses experience as a
guide as to what can be achieved,
and at what cost/timeframe.

My career (I'm 66 and retired now, (I even got a American Flag
flown over the White House at my retirement)) was this:
High School, photographer for yearbook, Wedding Photographer
College, Mass communications, TV, Student assistant on staff,
Instructed as permitted audio-visual college classes.
Short of credits after 3 years, went into USNavy, air traffic control.
Took CIE electronics 1st Class RadioTelephone License Course.
Joined FAA, as air traffic controller (Look on QRZ.com for wd8aam, bio)
after 7 years, took early computer class in programming (1979).
After 6 years, FAA sent me to school for mainframes, AND continued as
FAA Air Traffic Controller. Retired after 25
more years from FAA ATC/Computer Specialist.
I feel blessed for this Career, and especially,
since in High school, I graduated 236 out of 238 as
a D- (5 year) student, NOT caring but wondering
where I would find myself a job as a
productive citizen of the USA. What would the future hold? I found out.
The USNavy gave me the answer. And the training.

I just want others to know opportunities abound, you MUST seek them out,
and take advantage of the ones you can find. Especially when it relates to
training. Don't give up, the military is a GREAT character builder.
And training in many specialities.

After reading these entries, I just couldn't resist- I had to say something. To both Glen and Van, I salute you guys! You echo what I'd learned about what I consider as 'real-world electronics' -- much different from what they call 'electronics' today. I learned basic electronics in high school (for free!) what many are now learning for literly THOUSANDS of $$$! I think I learned more then than they are now. I too worked hard for even a 3rd Class licence (with a broadcast endorsement!). Wow, was that really special to me! No, it wasn't a 1st Class, but I had my foot in the door at that point. Today, I work in broadcasting--in TV and radio--with credentials; but it's an entirely different industry now; it's all about networking and computers. Still, my traditional broadcasting experience always seems to come in handy. I can do things in simple, practical ways that other so-called 'engineers' don't seem to understand. I owe a good part of that experience
to the likes of amateur radio. Broadcasting and ham radio used to go hand-in-hand, which is--sad to say--not the case these days. I hold fast to the good values I've learned from folks like Glen and Van. You guys were here LONG before I was even an embryo. (Hi) I think we need more guys like you to rekindle what ham radio should 'look' like, along with all the practical electronics knowledge that it embraces.

Van, I will echo what you said about Cleveland Institute of Electronics. Upon graduating from high school in 1958, I realized I needed additional education to be able to make a decent living. I had received a General Class ham ticket in my sophomore year. Those were the days when the General Class exam did not contain all multiple choice questions. You had to actually draw diagrams and write out answers for some of the questions. There were no “question pools” so you could never be sure what questions would be on the test or how they would be asked. However, I had a serious problem. I was very poor. I had raised and sold tomatoes and done simple radio and TV repair to get a Heathkit AT-1 transmitter and a used Hallicrafters S-40B receiver. My test equipment consisted of a cheap VOM and the tube tester at the local drug store. Going to college or trade school was out of the question. I lived in a rural area and scholarships, student loans, and grants
were very scarce or nonexistent. I couldn’t even afford correspondence courses that included test equipment or radios. I signed up for two CIE courses: one to train for the Second Class Commercial ticket and later for the First Class. The lessons were well designed and easy to follow. I found them exciting and I couldn’t wait for the next book to arrive. I had taken all the math courses offered by my little high school so I already knew most of the math except for trig. The CIE course provided a sound education in trig, and I became very proficient with the slide rule. All in all I ended up with a good, solid education in electronics and passed the FCC exams with flying colors. My voice had matured when I was about thirteen so I sounded like I was about thirty. With a book from the library and an old Webcor tape recorder I had trained myself to be a decent announcer. With my First Class ticket in hand, I thought my troubles were over, but that was
not to be. The local 250-watt AM broadcast station would not hire me because I had no

connections and had not been popular in high school. There were no other electronics job possibilities in my hometown. I went to stay with a relative in Dayton while I looked for a job there. It was there I found the downside to correspondence schools. I had no hands-on experience. My diploma from CIE and experience in ham radio was not enough. It seems the people with FCC licenses that got jobs had worked their way up in the field. They had not received their license just out of high school. Even with my knowledge in radio and electronics, I had to settle for minimum wage jobs that had nothing to do with my chosen field. However all was not lost. I was fortunate enough to find an area that was hurting for guys like me. That was something new called computers. Of course CIE did not cover digital electronics, but I was able to take a course at a community college that filled in that gap. With my background from CIE I was off and running. I graduated from the University of Dayton, became a software engineer with an international corporation, taught computer science at a community college, and worked as the operations manager at an FM broadcast station. My diploma from CIE still hangs proudly on my wall.

Subject: Re: [TS-520_820_530_830] Re: The hams of the future

Another way to pickup fundamentals of electronics is through the Cleveland Institute of Electronics, CIE using a correspondence course. I took the 'tube based' 1st class FCC license course back in 1969-1970 which was about $470 then.

Here's their URL: http://www.cie-wc.edu/

One thing I found was that they had a simplistic view of electronics, that made learning very fast. I learned mathematics/how to use a slide rule/calculator in four small books. I was amazing since I hated the subject of math in high school, this was SO easy; and the rest of the course went by almost too soon. And yes, I received my FCC license when there WAS such a thing.

The most amazing part was what/and the amount I learned in 1 year, vs what I learned in high school. NO comparison.

CIE is just one institution, there are several out their, google electronics correspondence courses.

I only wish high schools gave more import to electronics than they do now. I graduated in 2000 so I know I'm the pipsqueak of the group. As a sophomore in highschool I signed up for a communications electronics course, then the teacher retired literally right before the school year began. We had subs who treated it as a study hall for several months until they hired a teacher who turned it into a woodshop class. I kinda wish I had stayed in that now actually, I'm horrendous with working with my hands. The next year I had the opportunity to go to a vocational school in the second half of my day to an Electronics class there. Awesome teacher who retired from the Navy. Knew what he was doing and kept us busy learning. Then the second year I was there.. some stupid kid showed at his house drunk on Halloween, got picked up by the cops and he was forced out of the school, guilt by association. The guy they got to replace him turned the class into a computer class. Put us on the track to take A+ certification test. I just passed that test last year actually, I'm in computers now but I never went to take the test after graduation. That class is still a computer class. The local community college even stopped teaching electronics. I'd have to drive 30-40miles away to one that does.

I've been self-teaching myself for quite awhile. I've had an interest in it since before I got my Ham Radio license actually, and I got that in '94. Just wish people would take it a little more seriously around here. Guess if there's no job prospects around here, no one is going to care to teach it. That just goes along with the lazy work ethics I see these days, where people do just the bare minimum and don't care to put any extra effort.

Hi Mike,

Thanks for your reply. Just the fact there is any interest is a great first step. Your questions point directly at a few things that have to be overcome and decisions to made. The whole project will fail if any one or two of us "dictate" how things must be done. So let's see if we get a few suggestions about to do a FAQ and how it will be hosted.

73,

Online volunteer TS-820s tech support team:

Thank you for the encouraging responses.
Thanks for not telling me to "search." (I'm still reading through the 400+ messages you get when you search "no ALC!)

My wife (KD0FDN) laughs with (at?) me and this radio. She saw the old black and white youtube ham radio videos and said, "In 1950, 11 year old Jimmy could make a ham radio out of some shot glasses, a colander, an egg beater, and a chunk of barbed wire; Why can't YOU fix that thing?!"

Yes, we share a distinct sense of humor.

Mike,

I'd just like to add my 2c worth.

I am NOT licenced YET but I am studying. Personally I am finding it challenging as I am somewhat of an Electrical Numpty from the school of "if you can't see it you can't fix it".

Luckily I do have a brother who is a bit of an Electronics whizz and also a bunch of Electronics engineers at work who are patient enough to answer my questions..of which there are many.

Matters are compounded by the fact that I have a lot of other things to do with my time and there are never enough hours in the day. However I like the challenge and I am learning slowly albeit so far without an Elmer. In fact I have never even seen a ham working their rigs!

The mysteries of FM,SSB and the various antennas are still to be fully revealed and "lurking" here has its benefits but there will be more when I am finally licenced and can start transmitting. You can expect a lot of questions then although I'll do my best to nut it out myself first.

However there is another side of the coin. There are many people who love driving but have no idea of the workings of the internal combustion engine beyond what is required for day to day running. They are happy to let an expert tell them what needs to be done and to service their cars as required. I am sure there must be hams who enjoy the simple fact that they are on air and talking to distant places but who not fully understand electronics. They would probably be quite happy to pay to have someone come and tune up their rigs to improve their enjoyment. Similarly there would be many quite happy to buy an antenna and have it erected with little or no understanding of the physics involved.

Personally I am a DIY type of guy but don't mind asking questions if I can't find the answers myself. Sometimes is easier to ask an initial question to be set on the correct track than it is to spend hours wasted on wrong turnings leading to frustration.

At the end of the day however it is not so important what you say as how you say it that determines if the questioner will ever ask again.

73

I finally found my TS520 manual since I have been moving all my hobby stuff from one end of the house to the other, into a salvaged and remodeled kid's bedroom. Anyway the book sez TEN meters is where yoou do the neutralization !!!! sorry, it has been about 20 years since I did mine !

_____
From:
. The owners manual states that the neutralization should be done on 10 meters. I did it 4 times, and every time when moving down to the lower bands I would have the rig run away and blow the 115V fuse.

Well...looking at the questions , basic radio you wonder why they don't get
it...
BUT on the other hand, I am totally lost in the dark when the noobies start
spewing the stuff about the various digital modes and computer ham programs that
THEY grew up using !

So when I ask what the futz is a digigoombahboomer mark 7 firmware mod?????
 THEY wonder if I just jumped off the turnip truck ! Everybody who is Anybody in
ham radio should know all about the digigoombahboomer mark 1 thru 6, at least
!!!!
Tube circuits ??? forget that old stuff....
My $0.02 :D

To me using a hybrid radio,Kenwoods, it is like the first time that I got to
drive my fathers 69 Chevelle. She may start a little cold in the mornings
and she runs best after you let her run for 15 or 20 mins but you never
forget the ride. Alas I digress, I have noticed a general consensus in some
circles that are brow beating newer hams when a simple(to us) question is
asked. Some will say I had to learn from a book, let them learn it that
way.73 de K8BEC,
Bryan

Apologies to the list for the OT reminences.

At some point, you begin to forget more than you know. My first call was KN0KMY. In '58 I took the streetcar to downtown Kansas City to take the Novice test at the FCC office. Worked KC to Los Angeles with 2.5 W 6L6 single tube rig into a dipole tuned with a loop of wire connected to a 1937 Buick Tail light bulb, 579, my finest hour. Right after that some guy (I really wish I knew his name) saw me looking at parts in a radio store and asked me if I wanted some stuff. He gave me 4 wheelbarrow loads of WWII surplus, (it took 4 trips with dad's wheelbarrow to get it all from his station wagon to my shack, dad's basement) and I haven't been quite right since. Talk about an Elmer, and I don't even know his name.

D.

Stephen:

When I got my TS-820S it had no ALC indication. I asked the famous Ken about that and he recommended I start with the transmitter level diagram. That was an entirely logical response - and was a complete waste of time other than getting me familiar with some aspects of the radio.

I went through all of the Kenwood Service Bulletin info, one at a time, and found some things that way. As it turned out, one of the IF connectors was in the wrong position (not mentioned in the Service manual but instead in the Operating Manual), the usual resistors in the HV power supply were burned out, numerous transmitter adjustments were out of whack, the Carrier Frequencies were off calibration, the VFO tuning cap was shorting out and the SSB filter only worked on USB. And that's just the stuff that came as is and I did not break myself while trying to fix all the other problems or that simply failed spontaneously during the troubleshooting process.

And before the TS-820S I had already bought a TS-520 that would not transmit and fixed it! I thought the TS-820S would be just as easy.

The people here were a big help when I got stumped or needed something explained more clearly than the manual.

P.S. 11 year old Jimmy had it easy in 1950. I recently fixed three different 1960 vintage National receivers, one of which required a redesign of a local oscillator combined with an new alignment procedure that was unique for that set - and that was all a snap compared to the TS-820S.

Good Luck!

Amen to that. I started studying the ARRL Handbook with a 1948 version when I was 10 years old. The book was given to my by a friend of my dad's. I studied it to the point that the pages were all lose and several times I had to put them back into order. I studied enough to not only get my novice ticket but I also designed and built my own rcvr and xmtr. I WORKED. No one can ever quit learning by studying. That ARRL Handbook was given to me 61 years ago. I have never regretted studying it.

> When I give a response to a question, I typically include supporting statements so the person actually learns why certain steps are to be taken. I have also stated that operators should read the "Circuit Description" section of the manuals plus study the block diagrams. If they have any questions then they should come here and ask for an explanation. There are some who take it upon themselves to actually read and study this information but for the most part, many do not. If you want to learn you need to start learning the basic "first"! You can't learn advance subjects without having a thorough understanding of the basics "FIRST"!
>
> I will be glad to help anyone who wants to learn. If you don't understand something, regardless of what it is, don't sit like a bump on a log, ask for help. Don't expect me or anyone else to take hold your hand and always GIVE YOU THE ANSWERS! You, as a student, have a responsibility to "STUDY" on your own. You will not learn a darn thing if the answer are always given to you because you are too lazy to study! This may seem harsh to some but learning is a "2 way street".
>
> If any of your are interested in learning the basics, I recommend you buy and study the first 2 or 3 chapters in the 50s and 60s versions of the ARRL Handbook. If you can find it, buy and read the first 2 or 3 chapters in the "Basic Radio Course" by John T. Frye. If you think this information is "out dated" and you won't learn a thing by reading it, THINK AGAIN! Basic electronics does NOT go OUT OF DATE because it's the year 2011 and the information in the reference material provide above is dated 1950 or 1960!
>
> Again, if you have any questions, ask for help either here or e-mail me. Don't expect to learn it over night, in a week or month. It takes a lot of studying, reading the chapters over and over again, and asking lots of questions before you will learn it.

From: kd0fds
Topic: 30999 Message: 31045

Sure. There are probably 15 things wrong with my TS-820s, but I actually found and corrected my "no ALC, No TX output" problem!

So I started reading down the tune up process again, and was staring at CAR1 looking for test point #5. What is this? A broken wire at J27? I removed the filter card from the chassis and looked more closely. yeah. That wire probably should go to something. I don't think these ham radio things have too many "race parts" in them. ("Oh you don't need that left-over engine part after a rebuild unless you plan on RACING this engine.")

So out to the garage where the welder is kept...and I find my soldering iron. Zip. Wire stuck back in the hole.

Back into the basement computer lounge where the XYL is watching dancing with the stars and I put the old goat (the radio, not the XYL) back together. check to make sure dummy load is connected...tuning seems weird. Oh yeah, flip that slide switch from tune to norm. on to the next.
Switch to USB and IP on the meter...Idle current....check...Switch down to ALC and TUNE..flip the SEND switch. I think I saw the needle move...good sign. Do it again with hand on drive control...and WHAM! she tunes! Tuned up all the way and I see my 90 watts on CW again.

Only one "new" problem. The meter pegs on RF when I tune up all the way. I think I've read about that... Maybe tomorrow I'll check that out and get back to stable 1.

What was broken?
When you look at the board, the nicely labeled connector pin that goes to the solder pad with the broken wire is the TIF pin. Makes Sense! The RIF was OK and so was receive. , but the transmit couldn't work with no TIF wire hooked up to it. The wire was solid strand and shielded. The solid wire is pretty brittle and must have been bumped one too many times.

In summary: Thanks team. You didn't provide me with specifics to find this problem, you just kept me motivated. It turns out these things are a lot like the Austin Healey. "Always blame the mechanicals before you blame the electricals!"

I still need a frequency counter and probably a signal injector to get this bucket tuned enough where I would trust it on the air, but I did get a used oscilloscope tonight.

Not bad for a lawyer's son, eh? Keep smiling and thanks for the help!

31046. The Elmers of the future

Topic: 31046 Message: 31046

Given the profound changes in how we interact socially I am guessing that people on boards like this are the Elmers of the future (or today). While there may be a lot of criticize about todays social networking there is a lot about it that is wonderful. For example I doubt that you could get so many people who are interested in Kenwood Hybrids from all over the world and so many who are so knowledgeable in a room together every day without social networking.

Like Heathkit or Collins stuff? Easy to find experts on the net as well. The internet has become a wonderful tool for those of us seeking to learn from others.

A lot is lost by not being face to face, but the benefits are also enormous.

Kevin
KD0ILM

Hope I can find an old ARRL Handbook as suggested by Mike at the Hamvention. Any of the rest of you coming?

Only one "new" problem. The meter pegs on RF when I tune up all the way. I think I've read about that... Maybe tomorrow I'll check that out and get back to stable 1.

That's an easy one IIRC. Isn't there a pot that controls the amount of meter deflection in the RF OUT position? I believe that is just a relative measurement.

73, and continued success! Jim AG3Y

Jim,

You're right, an open "TIF" connection will cause complete loss of RF being fed to the RF Unit from the IF unit.

The receiver will work fine if the "TIF" wire is broken because the "TIF" connection is for "transmit only" and has nothing to do with receive.

Good job and I'm glad you found the problem.

As for the RF meter peg full scale, the RF VOLT pot is adjusted too high. Rotate it fully CCW and key the transmitter at full output into a dummy load and adjust the RF VOLT pot for a 3/4 scale indication. The RF VOLT pot and meter indication are nothing more than "relative" RF output indication, nothing more. The RF output is applied to a resistive voltage divider and diode circuit. The diode rectifies the RF into a DC voltage and that voltage is fed to the resistive voltage divider and the RF VOLT pot which the output is taken from the RF VOLT pot's wiper and applied to the RF meter switch setting. That's all there is to the RF meter switch setting, no watt meter etc, just plain old "relative" power indication.

73s
Mike

I agree with that too. Social networking is great; just need to use it constructively (like we do). SN (such as this users group) is indeed a wonderful tool. It's been a very useful resource for me. I think for us (and no doubt others), it helps to inform about what amateur radio is about. Hopefully others who have no idea about ham radio will be informed by these resources... My thoughts anyway.

Bob, KD5MHQ

--- On Wed, 4/27/11, kevin <kmx888@...> wrote:

Given the profound changes in how we interact socially I am guessing that people on boards like this are the Elmers of the future (or today). While there may be a lot of criticize about todays social networking there is a lot about it that is wonderful. For example I doubt that you could get so many people who are interested in Kenwood Hybrids from all over the world and so many who are so knowledgeable in a room together every day without social networking.

Like Heathkit or Collins stuff? Easy to find experts on the net as well. The internet has become a wonderful tool for those of us seeking to learn from others.

A lot is lost by not being face to face, but the benefits are also enormous.

Kevin

Good work. sometimes you just need a sharp eye to find something that doesn't look right in the circuits.
Mt TS520 has an adjustment on the left side of the housing along weith the VOX adjustment that varies the Relative RF meter sensitivity. I never had much use for this meter reading since I always have an RF wattmeter connected to the radio.
I prefer to monitor the Ip meter setting and reflected power on the external meter when I operate.
 That way I know to stop sending when a tree falls on my antenna

Sure. There are probably 15 things wrong with my TS-820s, but I actually found and corrected my "no ALC, No TX output" problem!
and I see my 90 watts on CW again.

Only one "new" problem. The meter pegs on RF when I tune up all the way. I think I've read about that... Maybe tomorrow I'll check that out and get back to stable 1.

Topic: 31051 Message: 31051

Hello,
I am a new member and this is my first post. I have a TS-820S that does not display frequencies on the digital display for the 20m band. All other bands fine; but when I change the band switch to 20m, the display just goes blank.

I had been having trouble with erratic digital display on all bands(aside from the blanked 20m), so I did some web research and learned about the fix of cleaning the varnish off the corner screw mounts of the circuit boards in the Counting Assembly Unit. I did this, and presto, the display on all bands was perfect - except 20m still blank!

Any ideas of cause and way to correct the lack of display on 20m?

Thanks and 73s
Scott

Scott,

Welcome aboard. Does the rig seem receive on 20M? I would recommend cleaning the band switch wafers on the RF board...and...the other in the final cage area. Make sure rig is turned OFF AND UNPLUGGED...let it sit for a bit...and check the HV capacitors for voltage before rooting around in/near the final cage area...there's about 900 volts lurking there. DEOXIT works well...along with some "canned air." This a good place to start...and sure can't hurt. There may be other problems...but try this simple thing first..... then let us know.....good luck.....

Scott,

You might check the 20 meter VCO adjustment on page 45 section 2-2 "Voltage adjust VCO" and page 52 section 5-2-1 "Adjustment of VCO Coil" in the TS-820 service manual. It's possible the 20 meter VCO signal level may not be sufficient for the Display Unit.

Hi All,

Here's a couple of pages discussing SSB signal quality which might be of interest. These are not exactly step by step guides but they do give a good insight into the reason why we hear both really good and really poor SSB signals on air.

A member of our local ARC recently became a silent key. His widow has contacted our club to dispose of his equipment at Dayton this year. He had a TS830s; however the power cable can not be located.
Because we want to test the rig before taking it to Dayton, we need a wiring diagram in order to make up a new line cord. One of our members has the necessary 12 pin connector so all we need is the diagram.
If someone could assist me with the information or a website showing it, it would be appreciated not only by our club, but mostly by the SK's widow.
Thanks es 73, WA8KIW, John Levo, Hillsboro, OH

Every TS-830 I have seen has always had a 2 wire AC cord.
The TS-820 however is wired using a Jones Cinch plug.
Are you sure you are referring to a TS-830S?

Thanks,
Gordon

My TS-830s has the 12 pin connector too.
It's the same as 'most' of the images of a back panel TS-830s on the internet....

I am attaching an image of the back of an 830s if it works, but google "TS-830s back panel" and it comes up with an image showing the 12 pin connector and serial number that reads TS-830s.

Cheers
Chris

HI Chris,

Attachments to the group using e-mail responses such as pictures, manuals and other files, are not allowed. This is to help prevent Trojan viruses and other bad things from getting into the system.

The TS-830S marketed for the U.S. does not have the 12 pin plug. A few 830s with the 12 pin power plug have made their way into the U.S., most likely due to private sales etc., but 830s marketed for the U.S. only have the 2 pin power plug.

From: howie wright
Topic: 31055 Message: 31063

I have owned two 830's that were purchased overseas, one in Sinapore and one in Japan, they both have the 12 pin plug, and also the versatile main transformer that can be wired for various differant ac supply voltages. They also have the removable rear access plate that allows for mounting the DS-2, DC to DC power inverter. Giving the 830 the ability to run off of 12vdc.

A member of our local ARC recently became a silent key. His widow has contacted our club to dispose of his equipment at Dayton this year. He had a TS830s; however the power cable can not be located.
Because we want to test the rig before taking it to Dayton, we need a wiring diagram in order to make up a new line cord. One of our members has the necessary 12 pin connector so all we need is the diagram.
If someone could assist me with the information or a website showing it, it would be appreciated not only by our club, but mostly by the SK's widow.
Thanks es 73, WA8KIW, John Levo, Hillsboro, OH

Does both tubes [6146B] have to be in the circuit to work or complete the circuit
Why i ask this question is i would like to take out one tube out and check the output then put it back and take out the other one and check its output to see if they have even output or to see if the output on both matches
would this work
will wait for feedback as to why i asked this question

thanks
Don

Don,

The 6146 filaments are wired in "series". Therefore, if you pull one of the 6146 tubes, the filament circuit to the other 6146 is now "open". In the old days, Christmas lights were wired in series. If one lamp burnt out the rest of the lamps would not light.

The final tube filament series wiring is shown on the hybrid schematics.

The filament is 6.3 volts at 1.25 A = 5.04 ohm load.

I cheated and put a 5 ohm 10 W resistor across the removed tube filament pins and it worked. However, the load impedance is now different and the plate tuning and loading will be different than with two tubes. Otherwise is works fine.

From: andy_westcott2004
Topic: 31069 Message: 31069

Hi guys.
Although my 520SE works well, I can't help wondering if there's any relatively simple way to reduce the internal noise the rig generates.

Modern metal film resistors for example are a lot quieter than the carbon ones used in these hybrids. Can any of the semiconductors be replaced with any benefit?

Any of you done this kind of thing and benefitted?
Thanks for any comments.

31070. cw filters for TS-830S

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)

Greetings:
I have a TS-830S in the shop getting renewed and would like to buy some cw filters for it.I do not really understand the importance of where a filter goes in the IF chain.
YG455C 500 HZ filter for 455KHZ if
YG455CN 250HZcw filter for 455KHZ if
YK88C 500HZ cwfilter for 8.830 Mhz IF

INRAD sells compatible filters. Which filters should I buy for the sharpest selectivity on 20 and 15 CW and why.I appreciate your patience for these simple questions.

From: w5rkl
Topic: 31070 Message: 31071

Hello Richard,

The sharpest INRAD filter for CW is the 250Hz filters. However, unless you intend on contesting and working DX Pile ups then I wouldn't install the 250Hz CW filters. I have the INRAD 250Hz CW filter in my Drake R4C, along with a number of other INRAD filters and Sherwood mods, and it is a rather sharp filter. It doesn't ring either and it really reduces adjacent frequency interference during pile ups. I don't work DX pile up but I bought the filter to just have it.

The TS-830 has "2" IF frequencies, 8.8Mhz and 455Khz. To use the filters properly you will need to buy both the 8Mhz and 455Khz filters. For example, for a sharp CW mode, you would need to install INRAD's #97 250Hz 8Mhz and #21 250Hz 455Khz filters. This will give you both 8Mhz and 455Khz CW filtering at 250Hz bandwidth.

For normal CW filtering, 400Hz, you would need to buy INRAD's #98 and #99 8Mhz and 455Hz filters. This would give you the best all around "general" CW filtering. Using these filters plus the IF shift you can reduce most adjacent frequency interference without having to go to the 250Hz filters.

http://www.qth.com/inrad/

Use the link above and select "filters" then select "Kenwood" then select "TS-830" and you will see the various INRAD filters offered for the 830.

Hi Andy,

Personally, I wouldn't do anything to the 520. There is no real "simple" way to reduce thermal noise in the 520. If you try other solid state devices in hopes of reducing receiver noise you could end up inducing more problems in your 520 and end up with a 520 that simple doesn't work or if it works, the performance could easily be much less than it is now.

In addition, if you do not have the test equipment and skills, don't try changing original diodes for "pin diodes". More often than not, replacing the diodes with pin diodes has very little, if any, affect on receiver noise. Most hams who say you should do this do not have the test equipment and the skills to make "before" and "after" tests to determine what, if any, improvements have been done by replacing original diodes with pin diodes. The link below has a short but informative write up about this.

http://w8ji.com/receivers.htm

Scroll down the page to the "Pin Diode Myth" section and read what Tom has to say about this Pin Diode non-sense.

Again, I would not recommend making any changes to the 520 and don't be fooled by others who tell you to change the diodes to pin diodes.

Last but not least, it is your 520 and whether you leave your 520 as it is or not is entirely up to you. I am only providing you an answer to your question and what I think about all this receiver improvement non-sense. Again, it's up to you what you decide to do.

Andy:

I have both a TS-820S and a TS-520. For the TS-820S I replaced a couple tantulum capacitors since they have known age issues that can result in stability problems, increased noise, etc, and the rig had a lot of problems I was trying to correct.

I have not looked at my TS-520 for the same kind of problems because it did not seem to be as noisy as the TS-820S and I was not trying to fix the other problems the older tantalums might have been causing. The caps were in the carrier module and the PD/VCO module of the 820S. In the case of the carrier module one guy even recommnded replacing a a few of the electrolytic caps as well as the tantalum cap and using larger values to provide better power supply conditions. Unfortunately for my spare PD board replacing the tantalum that can cause noise with a ceramic bead cap of the same value apparantly resulted in some frequency instability, so if I ever have to use that board I'll have to change it back.

If I were you I would look at the TS-520 service manual and see if there are any tantalum caps that might be failing and causing noise or other problems. Unlike the semicoductors, replacing the caps with modern equivalents is unlikely to cause any problems. And it probably will be easier than the transistors as well, although not very easy - those little caps are in there pretty tight! Fortunately the new modern electrolytics tend to be smaller than the old ones.

Good luck and 73's!

Richard,

I own an 830s, and have the Kenwood 500 hz and 2.4 KHZ filters in both IFs. They are not expensive if you keep an eye on QTH.com and Ebay. The results are astounding on SSB, and CW. With all the filters installed, you will be able to adjust the passband width down to as narrow as 150hz. I have owned a number of rigs including Ten Tec, and ICOM, and live a few miles from HRO where I can test all the new stuff, and I am still knocked out by the selectivity of the 830s with all of the filters.

I do not think that any of the newer rigs with DSP could do any better in the real world. The standard Kenwood Filters will do a great job!

Regards,

David

Thanks guys for your replies.
In the light of what you have both said, I'll leave well alone and accept the idea that 'if it ain't broke, don't fix it.'

It's just that I wondered if the old carbon resistors in the front end may be contributing to receiver noise and the unit could have benefitted from changing one or two in critical areas for the modern low noise metal film types.

Thinking about it though, band noise is so much higher than receiver noise that it can't really affect anything significantly.

Love the old radio, I use it almost exclusively on digital modes, so she'll stay as she is. :)

31076. 520SE NB board alignment question.

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-05-01 13:11:10 UTC
From: andy_westcott2004
Topic: 31076 Message: 31076

OK, I'm checking some of the simpler adjustment jobs I can do in my 520.

I'm having a disagreement with the manual though, regarding the NB board alignment. (X54-1080-10)

Part of the instructions say adjust T6 and T7 for a MINIMUM voltage reading at the collector of Q6, surely this is incorrect?

I can easily adjust for a PEAK in the voltage with T6 & T7 and the peak is well-defined at about 0.6 volts, but any setting other than this reduces the voltage, in either direction, making adjusting for a minimum meaningless.

Is it possible the manual I have contains a misprint and instead of 'minimum' it should read 'maximum'? Or maybe the circuit has a problem.

Guidance much appreciated.

Hi Joe,
I hooked up a short wire antenna and could receive signals on bands with a digital display, however nothing but audio hiss on 20m. I think it is a good starting point to clean off the band switch wafers, as you suggest. I will need to buy the Deoxit. I understand there are different types. Can you suggest the best variety and where to get it (e.g., Radio Shack or specialty electronics shop?).

Many thanks,
Scott

Hi Andy,

No the adjustment stated in the service manual is correct.

If you read the Noise Blanker circuit description then the noise limiter adjustment will make more sense.

Basically, Q6 controls the gain of Q3, Q7, and Q4. Q5 acts as a switch to, vary rapidly, open and close the signal path (through Q1, T4 and T5 to Noise Blanker's NBO output terminal) when noise pulses are present on the VFO mixer signal that is applied to the Noise Blanker. The VFO output signal is "always" applied to the Noise Blanker board. The Noise Blanker circuit, consisting of Q2, Q3, Q7, Q6, and Q5 is only activated when the NB switch is turned ON. With the NB switch turned OFF, the VFO Mixer signal appears at Q1 and Q2 but is blocked by the reduced gain of Q3, Q7, and Q4 and Q5 and Q6 are turned OFF.

Q6, when pulse noise is present, controls the gain of noise amplifier Q3, Q7, and Q4 by acting upon the rectified noise pulses through diodes D5 and D6.

When noise is present and the NB switch is turned ON, the VFO signal is applied not only to Q1 but also to noise gate Q2, then to noise amplifiers Q3, Q7, and Q4. The output of Q4 is then applied to diodes D5 and D6 where the noise signal is rectified into DC pulses.

The DC pulses are then applied to the base of Q6, turning Q6 ON. This causes noise amplifiers Q3, Q7, and Q4 to operate at maximum gain.

At the same time, the DC pulses are also applied to the base of Q5 causing Q5 to turn ON, grounding the center tap of T4 and effectively "opening" the signal path through the noise limiter, hence no output at the "NBO" terminal.

The length of time Q5 is turned ON is based on the fixed AGC type time constant of R3 and C7.

The opening and closing time periods of the noise blanker's signal path is based on the AGC time constant of R3 and C7.

By adjusting T5 and T6 on the Noise Blanker board with a "noise free" RF signal as stated in the service manual (the adjustment does not say to inject a signal with noise), you are basically biasing Q6 "OFF" (minimum Collector current) so the noise amplifiers Q3, Q7, and Q4 are at minimum gain.

A signal with noise will be applied not only to Q1, T4, and T5, but also to noise gate Q2 and noise amplifiers Q3, Q7, and Q4 and support circuitry. By opening and closing the signal path very rapidly, on noise peaks, the signal appearing at the Noise Blanker "NBO" output terminal will be noise free, or so we hope.

The noise limiter will not acts on all types of noise. The noise blanker is designed to acts on "pulse" type noises such as arcing from power lines and automobile ignition noises. Fast switching type noise such as found in computers and other electronic devices and

Corona noise, the noise limiter will be useless.

Another problem with noise limiters is the presence of what I call "Phantom signals", signals that "appear" to sound "raspy" on the frequency the 520 is tuned to. Those signals are typically not operating at the 520's operating frequency but rather quite a bit away from the 520's operating frequency. This is caused by the noise limiter's act to eliminate noise and is not an interfering stations on your frequency. Turning the noise limiter OFF will cause these "Phantom" signals to disappear. These "Phantom" signals can be caused by CW and sideband stations and are not necessarily resulting from "splatter". When the signal path is "closed", by the action of the noise limiter, the gain of the receive is at maximum for a very short duration. Why? Because the noise limiter output signal is "before" the crystal filter and the bandwidth of that signal is much wider than the signal that appears at the output of the crystal filters. Therefore, by the rapid opening and closing of the signal path through the noise limiter causes the receiver's gain to be at maximum (AGC control is on the IF Unit and "after" the crystal filters) gain. This results in those "phantom" signals to appear as though they are very close to your operating frequency when in most cases they are 5Khz to 10Khz away from your operating frequency. In most cases, these phantom signals are not caused by splatter but rather receiver maximum gain and much wider bandwidth of the signal being processed through the noise blanker. The bandwidth is approximately "500Khz" since the "RIF" 8Mhz (8.895Mhz to 8.395Mhz) signal bandwidth must be 500Khz wide (8.895 - 8.395 = 500Khz). As I said, the signal passing through the noise blanker is "before" the IF Unit crystal filters.

The following statement made in my recent response should say the following:

"When noise is present and the NB switch is turned ON, the VFO mixer output signal is applied.."

and NOT as original said, as follows:

"When noise is present and the NB switch is turned ON, the VFO signal is applied.."

I forgot to include the words "mixer output" to the sentence.

Sorry about that.

Actually, if you really want to see unbelievable filter action
(brick-wall, steep shirts, bandwidth adjustable from 0 to 20 KHz,
adjustable passband that's incredible), you should play with a FlexRadio
5000A. It's hard to go back to any other rig after you play with a
software defined rig.

Hey Scott,

The DEOXIT D5 is what is I use...the are others...but this has worked well for me. RadioShack used to have a small spray can...but I can not confirm that...I buy mine on-line from "Muscians Friend." They sell well...music stuff...amps..tubes..but have the cheapest price on the DEOXIT...5.0 oz spray....a little goes a long way...you can find "canned air" Wal Mart..COSTCO...and some other stores...that usually have computer/electronic stuff...the most common is "DUST OFF." Mike...W5RKL has a very good point...you may have a malfunction of the 20M VCO...but a good cleaning...is a simple & easy place to start. One or more contacts on the band switch wafer(s) for 20M may have "gunk" or are otherwise unable to pass a signal. The VCO adjustment..is not difficult...just a bit scary...the first time. Read the service manual section regarding this several times..look at the part(s) concerned and "GO FOR IT."......GOOD LUCK...keep us up on your progress

Hi Joe,
I hooked up a short wire antenna and could receive signals on bands with a digital display, however nothing but audio hiss on 20m. I think it is a good starting point to clean off the band switch wafers, as you suggest. I will need to buy the Deoxit. I understand there are different types. Can you suggest the best variety and where to get it (e.g., Radio Shack or specialty electronics shop?).

Many thanks,
Scott

One of the guys here at work has been asked to get an idea of the value of A TS 820S and a (KENWOOD)Trio 9-59D Receiver

Not only am I new to ham radio and so know very little about value of rigs but there are few hams that I know who might be able to give me an idea.

I appreciate that much will depend on condition but I am assuming them to be in good to fair condition to be safe as I have not seen them myself.This is probably the best place to get a response from someone in NZ about the value of one or both rigs.

Even an idea of US values would help. I could even be interested in the 820S myself but I would want to be sure that I was not ripping the widow off through ignorance. I'd also like her to have an idea of value if anyone should turn up and make an offer.

Any ideas would be most appreciated

I recently purchased a near mint condition TS-820S for $550. When I say mint, I mean mint... full output on all bands is 100 watts+ and the rig is clean as a whistle with original box and packing. That price also included an equally mint MK-50 microphone with original box. I can't help with the receiver you listed.

Hi,

I'd say trying to compare prices with NZ and what folk pay for stuff in the US would be difficult.

The best way iMHO of getting an indication of price would be to take a look on Trademe. There is quite often a bit of 'Vintage' Kenwood kit on there.

That will give you an indication TM prices tend to be a 'bit' higher than say a junk sale or ham fest table price as TM garners a larger audience.

HTH

If I wanted to play with a computer instead of a radio, I would consider a flex, but this discussion is regarding a gentleman who wants to choose filters for his TS-830S, not buy a flex.

Regarding SDR, I built a Soft rock, and it was interesting, but I still like my 830S.

All is not perfect in the flex world either. Just read about all the issues folks have had trying to get it to work, and the problems that they have had on the computer side of it. Heck They are still trying to get the 1500 to work on CW, that's why there have been so many used ones only weeks old up for sale.

I gave $400 for a mint condition TS-520S and I thought that was a fair deal. It was spotless and hard to believe it was that old. It came with all the boxes, packing and manuals. The owner also included a nice MC-50 microphone with it's box and manual too. I have seen final Ebay bids on junk (according to the pic) radios that were insanely high and low bids on supposedly nice radios.

Actually Pete & David, I think it would be interesting to present your views on the performance of older radios with crystal filters compared to the modern IF-DSP filter technology... Personally, I don't think DSP capability is quite there yet, but is very close. But I could be wrong... The newest radio that I have is a TS-450SAT. The oldest is my D-Twins. And the 520, and the 440SAT. I love them all, but for everyday use, the 450 (full complement of filters for CW & SSB) wins, hands down! Now, if you want to lend me a Flex for a few months, it might (or not) change my mind!

Comments??? Or maybe this group shouldn't participate in discussions about new technologies??? Just my drivel...

Cheers, 73,
Chuck, WA3CEJ

Chuck,

I have owned an Icom 746 Pro, and when it was cranked down to a narrow bandwith for CW, the signal sounded like breaking glass. I also owned a Ten Tec OMNI VII, and the dsp on it did not seem impressive, and these are modern rigs.

The two best sounding radios I have owned, are the Ten Tec Corsair II, and my present rig the TS-830S. Both of them had a full complement of crystal filters, and I could listen to them for hours on either SSB or CW without fatigue.

I believe that the two worst things that have happened to Ham Transceivers are General coverage which moved the first IF to a high frequency where the availability of narrow crystal filters at a reasonable cost does not exist, and the use of microprocessors in the same radios to narrow the IF signal.

By going to DSP, the radio manufactures have been able to save a considerable amount of money by eliminating the cost of either crystal or mechanical IF filters, and the result are rigs that sound like crap! It's all about the cost of manufacturing.

Have you seen any of the newer up conversion radios that offer a 500hz filter in the first IF where most of the IMD takes place? Look at the new Kenwood 590S. The narrow 500hz filter is only offered on the bands that are down conversion. The result is the 2khz dynamic range is very degraded on the up conversion bands in the same radio.

Some idiot just did a review of it for this months QST, and saw that the 17 meter rating (up conversion all dsp) on Sherwood engineering's web site was only one step under the 20 meter down conversion rating. He forgot to mention that the 17 meter results were just there for comparison, and the 17 meter results were way down the chart for actual performance. Here is a radio with both up and down conversion, and the performance of the down conversion with true crystal filters comes out way ahead.

If you think I am making this up, just look at the width of the few filters offered for the current up conversion general coverage rigs today. if they re offered at all for the first IF, they are 15 to 25 KHZ wide, and they rely on dsp to make up for it.

so much for my rant. I need to go to work in the morning so I will go to bed.

David - KE6YX

David,

Nicely presented and clearly thought out. And the first paragraph lends a lot of credibility! Thank you for your response. Maybe it doesn't belong here in the Hybrid group, but I can't think of another group where I could have received such a meaningful reply...

I do hope to hear from "the other side"... Just for balance...

Thank You!!

Cheers, 73,
Chuck WA3CEJ

31091. WWV reception

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-05-02 15:18:31 UTC

Topic: 31091 Message: 31091

Let me first thank many of you for helping get this basket case TS 520s working well once again. It has been fun.

The 80 meter crystal fixed the problem on that band and 160 meters now produces 95 watts output.

New lights have been installed and I can see again! HI HI.

One thing I just noticed. WWJ setting does not work. No receive but I do hear a weak 25 kc calibrator signal. The schematic shows adjusting coils for that band. My radio does not have these adjustments. Did Kenwood make some TS 520s without the WWJ receive but leave it on the band select switch?

Dennis n5dpk

31092. TS-520 and TVI

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-05-02 15:38:00 UTC
From: ki4ax
Topic: 31092 Message: 31092

Mike and the group: I seem to be having a problem with TVI. I am using a TS-520 and have been operating around 14.200 and blank the TV out when transmitting. I am using an inverted v antenna with a 1:1 balun at the feed point. The antenna is cut for the band/frequency that I am operating on. The 20m inverted v is in close proximity to the TV antenna... I have not measured the distance but it looks like 10 to 15 feet. I have operated other antennas, in the past, on different bands and at further distances from the antenna and have always had a problem with TVI. Anyone have any ideas or have had similar experiences? I have been looking in the manuals and schematics for a TVI filter but have not been able to ID anything as such. I know TVI can be fickle but would like to hear about some solutions (the simpler the better) that others have had success with and about any inherent problems with the TS-520 pertaining to TVI, if there is any.

Thanks,

Dan KI4AX

One of the guys here at work has been asked to get an idea of the value of A TS 820S and a (KENWOOD)Trio 9-59D Receiver

Not only am I new to ham radio and so know very little about value of rigs but there are few hams that I know who might be able to give me an idea.

I appreciate that much will depend on condition but I am assuming them to be in good to fair condition to be safe as I have not seen them myself.This is probably the best place to get a response from someone in NZ about the value of one or both rigs.

Even an idea of US values would help. I could even be interested in the 820S myself but I would want to be sure that I was not ripping the widow off through ignorance. I'd also like her to have an idea of value if anyone should turn up and make an offer.

Any ideas would be most appreciated

Well here is the bad news that is intended to counter the good news. Yesterday afternoon I spoke to the former owner of a long time ham radio gear store in Vancouver, BC. I say former because though there are still radios being bought and sold, there was not enough traffic to pay the rent so the store front has become former, while the owner has retreated to his garage since the beginning of this year (2011). In the past years Stan really provided a valuable service to the west coast ham community in recycling used ham gear on the shelves alongside his newer offerings. The last two consignment TS-820s went out the door as movie props because no homes could be found for them. They were incinerated inside the special effects stage.
He confirms that while there was interest in the old ways, not one offer over $100.00 to $150.00 for a complete station. Sorry guys, only the faithful will pay to play.
YMMV, but remember how old this stuff is. It will take a lot of elbow grease and some money to bring everything up to the values we would like to see. Cheers

I paid a $135 adoption fee for my tech special TS-820s tranceiver only.

I would say the radio was in "partially working condition." I've read or seen pictures of worse and it did actually turn on, so I would call it "poor" condition. Just a step up from "bad" where a unit won't even power up.

With the help of this group, I hope to actually make a contact very very soon on the repaired radio.

Over here the TS820 does 300 to 400 Euros, depending on condition, the 9R59 does 100 euro max. In the USA they tend to be cheaper, around the same price in $$.
I monitor the dutch sales for years now, and the prices are going up, some 10%/year, so it is a good investment.

YMMV,

Dennis, I believe you mean "JJY/WWV" not "WWJ".

JJY/WWV band switch setting has it's own antenna transformer T5 and RF amplifier Q5, it's own local crystal oscillator Q8 (23.895Mhz crystal), and it's own mixer transformer T4 and mixer Q4. These circuits comprise the WWV/JJY RF Unit initial signal path and processing stages.

With the band switch set to WWV/JJY, the 15Mhz signal flows through trap coil T6 then through JJY/WWV antenna transformer T5 to the RF amplifier Q5 where it is amplified. The amplified signal is then applied to mixer Q4 where it is mixed with the JJY/WWV local crystal oscillator signal (Q8), 23.895Mhz, producing a sum and difference signal, where the "Difference" signal, 8.895Mhz (23.895 - 15.000 = 8.895Mhz), becomes the "RIF" signal that is applied to IF Unit over the "RIF" signal path.

I recommend using a signal generator set to 15Mhz, inject the 15Mhz signal at the 520's rear panel antenna connector (SO-239) at a low level, and trace the sig gen signal through the JJY/WWV signal path to locate the source of the JJY/WWV problem. Since the 520 works on other bands, the problem is limited to the JJY/WWV signal path and associated JJY/WWV components.

To follow what I have stated above, study/review the RF Unit schematic in the 520 service and operator's manuals.

Mike, thanks very much for your excellent decription of the way the noise blanker circuit works, and your description of the phantom noise this type of circuit can generate.

As an update and in the light of what you had written, I think I must have been measuring the voltage at the BASE of Q6, not the collector, hence the 0.6 or so volts I was seeing. This of course would be at a maximum with T6 and T7 peaked, which I was observing.

I'll have another bash and measure at another point - maybe Q6's leads don't conform to the pattern I was assuming.

I picked up a TS-820s locally in Indiana for $300 last fall. It's not what I would call "mint" as there are some minor scuffs on the lid, but everything else is flawless and it works great.

I think it was worth every penny.

I know that on the TS-820S they use a 15MHZ WWV frequency while on my TS-520 the WWV frequency is 10MHZ.

Did they go to a 15 MHZ WWV freq on the TS-520S?

Thanks,

Robert

I would love to hear the reasons why we should restore and keep these radios in action. When I was a kid in the late 70's and early 80's I remember drooling over the ads for them. I know their on-air sound is still unbeatable yet today. Im sure there are other advantages from the old-school circuitry and designs. Anyone care to add to the list?

Exotic or highly specialized tools and test equipment are generally not required to repair them. Unfortunately, the older they get, the harder it becomes to sometimes find unique parts for specific models.

It was the 70s, when analog technology was at its peak. This is recognised in the audio equipment of the period which is also revered and widely collected. Microprocessors appeared shortly after our hybrids were designed, heralding digitally controlled radio (and digital everything else). Digital gear tends to exclude the user - it doesn't allow the freedom to play with it as much - so it was the end of an era in that sense as well. Beautifully designed front panels - lots of knobs that you can feel are actually doing something - so there's an aesthetic and touchy-feely sense to them which is very appealing to the user. Very human radios.

The reason I bought first my TS-520 and fixed it and then my TS-820S and fixed it as well is that you will not find better - or even equal - performance for the price.

I also have a Heathkit HW-100 I am - slowly - working on to get operational. But while there is an aura about the American-made Heathkits that nothing else has, I think that at its best that rig will never come up to the performance of the 520 and 820, and it is only a little bit cheaper than the Kenwoods at today's prices.

Topic: 31114 Message: 31114

Thanks to those who responded to my recent request for the wiring for the TS820s power cord. A new cord was wired but the rig still does not power up. No 120 power is getting to the transformer. The switch and fuse check OK. A Kenwood commercial radio tech is currently looking at the rig and believes there may be a wiring difference between the TS 820 and the TS820s. Any tips or suggestions? Thanks in advance.

There is NO wiring difference between the TS-820 and the TS-820S
Be sure to look at the Cinch Jones connector carefully and wire by the terminal number, not by looking as some of the views shown in the manual are actually the reverse side.
The terminal numbers would be correct though.
here is the wiring
http://www.n6wk.com/kenwood/TS-820S-%20High%20Res%20Schematic.pdf
Bottom of page 1 towards the Left side shows the PLUG wiring. The rig wiring for the plug is over on the bottom right of page 2.
Be sure to check S-16 Power switch, to be sure it works.

I feel they represent the last line of equipment where a novice could look inside and actually recognise some of the components.

With modern LSI and surface mount designs this is not the case - the circuit boards look... boring.

Inside a Kenwood hybrid you can actually see it working, you can see the variable capcitors being moved by a shaft or delicate chains and best of all, those glass thingies that get hot!

Besides by beloved 520 I also have a couple of 430s, these latter radios probably being the most recent TX equipment I will ever buy - I just do not like menus where you have to dig deep just to alter what should be accessible via a front panel knob.

Then there's that smell...
Open the case and sniff the circuit boards - that's REAL electronics. :)

Besides the outstanding performance the old Kenwood rigs provided, I think there was more room for quality construction, and quality was important in those years. Now everything is so competitive that all the engineering is a compromise between performance vs low cost, with no room for cosmetics. The Kenwoods were good design, quality construction, and beautiful design, and always worth restoring.

I also like the performance of the current black box rigs, but I hate looking at them. :-)

The Kenwood hybrids are like a 52 Mercury or a 69 Chevelle...classics. They were built during the era of quality. That is why they are still around. The receive was outstanding, the output power was above average, and most of all easy to operate. You would be hard pressed to find a heartier tube than the 6146's. They had a really classy look to them and the audio is hard to beat. I have owned an 820s, 830s, and a 520. I currently own the 520 and kick myself for getting rid of my 830s. Someday I will have another 830s.

Less expensive, better sounding and better quality than the new stuff.
Plus no menus, not digital (ok CW--the original digital mode), and just plain fun to use, restore & repair if needed.
73,

Bill

I would love to hear the reasons why we should restore and keep these radios in action. When I was a kid in the late 70's and early 80's I remember drooling over the ads for them. I know their on-air sound is still unbeatable yet today. Im sure there are other advantages from the old-school circuitry and designs. Anyone care to add to the list?

Greetings group,

A short time ago there was a message thread concerning the numbers on the various circuit boards. This involved the number(s) on the FOIL side, I guess it denotes production changes...and from what I understand some boards are not interchangeable(same model) unless the number on the back of the board is the same. Is this correct?

Andy ,

I agree whole heartedly , I have a TS 520S, and when I am asked about my Radio , other Amatuers congratulate me on the choice of SET.

Thes HYBRID sets are maore forgiving with high antenna mismatch, have better transmit and rec audio than modern solid state equipment.

Fine some do not have all the bells and whistles, but it is a joy to operate a set with KNOBS and not KEY PAD.

MAY THEY LIVE LONG AND PROSPER.

I feel they represent the last line of equipment where a novice could look inside and actually recognise some of the components.

With modern LSI and surface mount designs this is not the case - the circuit boards look... boring.

Inside a Kenwood hybrid you can actually see it working, you can see the variable capcitors being moved by a shaft or delicate chains and best of all, those glass thingies that get hot!

Besides by beloved 520 I also have a couple of 430s, these latter radios probably being the most recent TX equipment I will ever buy - I just do not like menus where you have to dig deep just to alter what should be accessible via a front panel knob.

Then there's that smell...
Open the case and sniff the circuit boards - that's REAL electronics. :)

Thanks for your input guys.

I have passed on the comment verbatim and suggested that, although I was interested I could not offer what I considered a reasonable price and that he might like to put them up on TradeMe (local Ebay) with a reserve and I would be happy to put in an initial bid to get things going.

He has countered with an offer to me to take the whole lot for $NZ200 and I have accepted and will take them tonight.

I am not sure that I actually want the receiver myself - I will wait until I have it in my hands and decide. If I don't keep it and sell it on then I will make sure he gets the money that I get for it.

Hmmm....I only really wanted the 520S when I started getting interested but somehow I now seem to have an almost full set with a 520S,530S &820S...and I still do not have my Certificate or a VHF/UHF rig. What goes nicely with the sets I have? Decisions, decisions.

Oh well as a couple of older hams have said "You can never have too many radios"

I hate to break the news to my XYL as she is already complaining about the PCs I have collected...time to rationalise I think. Maybe I need to splash out on a set of HS5 headphones now as she is complaining about me drowning out the TV...or maybe I should move out of the dining room and into the study

Back to my study for the licence

Just me 2 cents. I own a wonderful TS-530s and its still ticking. The audio from it and out of it is outstanding. Its easy to tune to jump from band to band, yes its a learning curve, but so much easier than digging for menus in the newer radios of today. Someone mentioned its like driving a 52 Merc or 69 chevelle, lets add a 56 Chevy Convertible to that feeling.

Morning Joe,

What you are referring to is my comments about replacing boards in the hybrids and my experience replacing the AF AVR UNIT board in my 820.

The 820 service manual, page 57, shows a schematic and transparent picture of the AF AVR UNIT board. The schematic is for an AF AVR UNIT board with a foil side "J25-1381-13" number BUT the transparent picture is for an AF AVR UNIT board with a "J25-1381-03" foil side number board. These 2 boards are not interchangeable even though they will fit in any 820 and the plugs will plug into the board in any 820.

I said it "appears" that the foil side numbers indicate differences in board circuit design and when replacing boards, make sure the foil side board numbers are the same.

Hi all,

I am a new TS830 owner , I have a bassy voice and audio with the microphone MC35 is muffled, I saw that there was a change in the files of this group to improve the audio by changing C106 (.015-microfarad) IF unit with a new .001-microfarad capacitor.
Someone he made the change and is it effective ?

Many thanks

Use a plastic rod or similar non conductive screwdriver etc. to tap on items in the signal path. If you suddenly get reception when tapping on a particular component, turn it off and resolder that part. That's how I fixed the same wwv problem on mine. if no joy, then break out the oscilliscope and trace the injected signal to find the problem.

over the years, with unequal coefficients of expansion and contraction, its not unusual for joints to work loose.

About one year ago I acquired a Kenwood 820s. The condition is good and I use it regularly. I like this radio a lot but am not a tech and have no idea how to service it. My idea of servicing anything is to get a bigger hammer. So I will leave it to the pros. A full restoration is not needed at all. I think tune up is in order. The radio does drift off frequency a bit even after hours of operation, not a big problem but not sure if this is common. I think new tubes are in order as I am sure I am not getting full power. I also don't think I am getting full band coverage on each band, mostly 10 and 15 meters. Does anyone have any ideas for work to be done when I have a tune up done? Some day I would like to upgrade to a 830s Gold Edition that is in excellent condition and keep the 820s in reserve. Thanks for the help !

The 830 has an audio response between 400Hz to 2.6Khz. Since your voice tone is primary bass frequencies, changing capacitors will only cause the low end frequencies to drop off sooner than 400Hz. I wouldn't change anything in the 830, leave it alone.

Hi,

I have the 599 Twins. I have used 520's and 820's - usually at Field Day. There have already been some very good comments about these radios. It is possible to get better receive performance but it's not trivial. I am not really familiar with the 530/830 radios but I like to dig out really weak signals in the CW mode. I turn off the computers and anything else *digital* that is under my control because I can hear the background 'noise' drop when I do. That is far below anything that moves the S-meters. Did you ever hear about QRP operation?

In my experience the newer gear automatically selects the receive filter for you (because you are too dumb to make your own choices). I often open up the filtering and my R-599 allows me to use whatever filter I want (I have a full set of filters). Sometimes it's less fatiguing to use the gray filter between the ears than the narrowest filters in the radios.

The transmitters are pretty rugged and reliable. We can get parts without too much trouble. I have already had to make substitutions for some of the solid state parts. I think that an IC failure would only require a little bit of study to select a substitute or other workaround.

I have radios and test gear here made in the 30s, 40's and 50's and all of it still works just fine. Obviously gear that old is subject to failures but also we can get parts. It's fun and easy to use all of those oldies. How long do you suppose the fancy new radios will last? My Kenwood was made over 40 years ago. Where do you suppose the new computer controlled, self operating radios will be in 40 years?

Dennis,

It is quite possible a previous owner has messed with the JJY/WWV RF Unit adjustment which will affect the JJY/WWV receive signal level.

Since you "can" hear the calibrator signal with the band switch set to JJY/WWV then I would check the JJY/WWV RF Unit alignment first before doing anything else. Do you have the 520S service manual? If not then I recommend downloading it from Gordon's website;

www.n6wk.com/kenwood/

and review the alignment instructions.

Is this on SSB or CW/??
CW key down, loaded and dipped Plate current 200 MA on any band below 15 M
should yeild 100 W output on as known good wattmeter,
SSB on voice peaks on most watt meters about 20-30 watts is normal, much more
will be distorted..

Hi,

Before I got my General license I snapped up my TS-520 with matching vfo, speaker and the Spectronics DFD-K nixie tube digital display.
It was in great shape, just needed a normal cleaning and deoxit.

I got the radio for the educational factor, you've got to work a bit
to get the radio tuned instead of using a keypad on the new radios.

I get a kick out of using PSK with the 520.

I also have the 530 that I also enjoy using.

This change slightly raises the high frequency audio limit and makes the radio be slightly more full and less pinched. I think that this change would slightly benefit almost any voice. It will help some but I do not think that it will totally solve your problem.

If your mike is not an MC35-S it is the wrong impedance for a TS 830.
The MC 35-S is high impedance and is the correct match for your radio but the MC-35 that is not the S model is 500 ohms and will be a bit weak on your radio.

Even the MC 35-S is probably not the best choice for your radio. Heil sound can provide you with a good sounding mike for your voice. Be sure to tell them what radio you have and your problem with a bassy or muffled sound.

There are other solutions. A Astatic D-104 will be higher pitched. A non amplified one will be extremely higher pitched on your radio. It may sound too high or thin. A D-104 on a amplified stand will still be higher pitched but not as much. A D-104 with the FET mod that is in the files section of this group will be flatter yet but still have lots of articulation. If you do go with an amplified D-104, use the TUG-8 stand and not the TUG-9 stand. The TUG-9 stand does not work as well although it can be modified to act like the TUG-8. It is a bit of work to do.

A Shure 444 or a Shure 444D will have a higher response than the MC-35 and may be a good choice. The best choice of the two probably would be the 444 that is not the D model. It is high impedance only. The 444D is dual impedance and seems a bit flatter. The D model should be run on high impedance with your Kenwood.

Some of the very old Shure mikes, both desk and hand mikes from the 60s were ceramic and were high impedance. Ceramic mikes have a great deal of high frequency rise. Not all ceramic mikes were high impedance but most were. These were used on very olde CB rigs especially tube type, and commercial two way radios. Some very early PA paging mikes were also of this type.

Last but not least, if your MC-35 is the S model, try placing a .02 microfarad capacitor in series with the live mike audio lead. As a temporary test that can be done at the plug. This will drop the level a bit so you will need to increase the mike gain.

I doubt if the MC-50 or MC-60 will help much but if you can borrow one, try it. It should be set for high impedance. Note that some of the MC-60 mikes had a wiring error inside of the mike itself. This results in weird sounds, RF problems, and bad audio, particularly with the pre amp on. It can be fixed, contact me if you run into this. The schematic on the MC-60 instruction sheet was also in error. Not all MC-60 mikes had this problem and it was more frequent in the MC-60 A. The MC-50 did not have this problem.

Grab mikes that are laying around and try them. I knew a ham that had fantastic audio and he was always asked what mike he used. It was a early 1960 vintage curled cord PTT, Lafayette Radio Ceramic hand mike that sold for $12.50 US new and came on an olde Lafayette HE-20C CB radio.

Subject: [TS-520_820_530_830] Audio Improvement in TS830S

Hi all,

I am a new TS830 owner , I have a bassy voice and audio with the microphone MC35 is muffled, I saw that there was a change in the files of this group to improve the audio by changing C106 (.015-microfarad) IF unit with a new .001-microfarad capacitor.
Someone he made the change and is it effective ?

Many thanks

Last night, about 3AM ET I make my first ever Australian contact, but I seem to have gotten his cal sign wrong and doesn't show up on QRZ.

I'm wondering if there's a good way to record contacts (probably to my PC since it's on the same desk) so when something like this happens again, I have a better chance of getting the callsign from a recording later.

any suggestions are welcome..

Kent

Kent,
what was his call (as you copied) and what time UTC?

I wrote it down as vk5bz, 06:54 utc on 14.140MHz. I guess his accent threw me off. I asked him to say his call again, but I guess he didn't hear me and went qtr shortly afterwords. I heard him say something about my audio (keep i mind I just got the TS830 on the air, so I'm not use to setting it all up) but he did read my call back ok.

At the very least, I know I made the contact, and that's what matters most. It sounded like it was a regular meeting time for a groups, so I'll try to listen in again around the same time tonight and might get lucky..

HI WALT :
DO YOU HAVE THE CORRECT WIREING PINOUT FOR THE MC 60A? IF SO, MAYBE IT WOULD BE A GOOD IDEA TO POST IT FOR THE MEMBERS OF THE GROUP. IT SEEMS FROM PRIOR POSTINGS THAT MANY MEMBERS OF THIS GROUP HAVE HAD PROBLEMS WITH THIS MICROPHONE BECAUSE OF THE INCORRECT WIREING.

Kent...

I use the SignaLink USB to record and playback - but on my TS-940 using
Audacity. I would imagine it would work
with any radio including the TS-830. Also should work with any sound
card. I would use isolation xformers with just the soundcard though.

I made my own interface for PSK31 to use with the TS-50 I have been using (on loan to me). I'm waiting on a couple 4 pin connectors in the mail to rewire it to the TS0830s, but it doesn't use transformers, just a couple resistors to control signal levels. but with the voltages in the hybrid, I think I would be safer adding a couple isolation transformers now. Just have to see what I can find in the surplus store or my old parts box of stuff..

I figure I can either tie it in to the external speaker I use now, or see if there is a line level output available in the manual.

thanks

This is a shunt capacitor that I recommend changing. The original causes too much high frequency roll off even below 2600 Hz. Decreasing it's value as I recommend allows more highs in the higher end of the 400 Hz to 2.6 Khz bandpass.
This is not a wide ESSB thing.

The 830 has an audio response between 400Hz to 2.6Khz. Since your voice tone is primary bass frequencies, changing capacitors will only cause the low end frequencies to drop off sooner than 400Hz. I wouldn't change anything in the 830, leave it alone.

I wrote it down as vk5bz, 06:54 utc on 14.140MHz. I guess his accent threw me off. I asked him to say his call again, but I guess he didn't hear me and went qtr shortly afterwords. I heard him say something about my audio (keep i mind I just got the TS830 on the air, so I'm not use to setting it all up) but he did read my call back ok.

At the very least, I know I made the contact, and that's what matters most. It sounded like it was a regular meeting time for a groups, so I'll try to listen in again around the same time tonight and might get lucky..

On SSB you do not get a true power output indication because the output power varies with the mike input. The only way to get an SSB power output indication is to feed the mike input a tone, like 1000 cycles, adjust the mike gain, and read it that way.

Also, even on CW if you are not running the output into a good dummy load but into an antenna you will have difficulty getting an accurate power indication because higher SWR affects the RF power indication.

If you have RF power indicated on SSB without any mike input then you have a carrier balance problem that we can tell you how to adjust that out.

Good Luck!

George,

You didn't say what make and model of watt meter you are using. Most, not all, watt meters used by hams are not peak reading watt meters but rather are average type watt meters.

An average watt meter will only display about 20 to 30 watts from the transmitter on voice peaks. This is normal and should not be considered a reason for replacing the tubes.

If you are not using a peak reading watt meter and your watt meter shows 50 to 60 watts then you most likely have the MIC gain turned up too high and with the front panel meter switch set to ALC, the meter pointer is most likely displaying a significantly higher than the max ALC scale indication.

You also didn't say what make and model of microphone you are using. Does your microphone have an amplifier adjustment or is it a Kenwood microphone such as the MC-50 which is a very good microphone for the 820?

Hi Chris,

I think I have your typos sorted out and you are asking about test/measurement gear for working on tube radios. Most hams have or can get a Digital Multi-Meter (DMM) almost anywhere for cheaps. Those usually have reasonably high input resistances on the voltage ranges but be careful about the maximum voltages. Our hybrids and many other transmitters have DC voltages approaching 1000 (one thousand) volts and more than a few transmitter tubes exceed 1000 volts. Your DMM won't be happy. The DMM is convenient for reading DC voltage levels in solid state circuits. The resistance ranges are also convenient.

A vacuum tube voltmeter (VTVM) or it's FET equivalent will have a high input resistance (~10 MOhms) and you should get one with the old style analog meter movement. Most VTVMs and some FET VMs have voltage ranges up to 1000 or 1500 volts. That needle swinging upscale and then back down as you are tuning a stage for a peak (or dip) is much easier to use than any winking, blinking DMM. Used VTVMs in working condition are not expensive. The V-O-Ms with analog meter movements are *NOT* in the same class.

For transmitters you really can't get around having some kind of RF wattmeter with decent calibration. One that will handle the power levels you expect from your radios. We are amateurs and we don't really need lab grade gear but the better accuracy you can get the better your results. Don't obsess over decimal points at the 100 watt level. I have some Bird wattmeters here and a military unit as well. Most of the time I use a small wattmeter/swr bridge that was intended for CB use. It has a 10 watt range and a 100 watt range (even though CBs are not supposed to put out more than 4 watts). There are internal pots for "calibration". The scales are not linear but logrithmic to read directly in watts. I used a HP scope to set the two scales. Such wattmeters can be home built or found at flea markets..holding down the expense.

My HP scope runs flat up to 75 MHz and there are others in the HP and Tektronix lineup that are inexpensive and will run flat up to 150 MHz or higher. If you want to look at digital and HF signals you want one that will go into the VHF spectrum like that. Older publications suggest you can get by without a scope but those were written when any useable scope would cost you a years wages (or maybe 10 years). A picture is worth a thousand words!

You can make sweep signal generators and wobbulators. There is a lot of info on the internet about those. For filter alignment you'll want one that is solidly built and reasonably stable. That 500 kHz wide I.F. "bandpass" filter in the hybrids demands a sweeper. Lucky for us that circuit doesn't need tweaking very much. The Heathkit type signal generators are maybe okay. In my experience the tuning rate is way to fast, they drift muchly, and output levels are not very well calibrated. Some of the mil surplus signal generators might be a better choice (I do have some Heath units). You can build your own signal generators, too, maybe based on a Heathkit.

There are lots of other toys but the meters and a scope will get you off to a good start AND they will help you build other tools. Homebrew spectrum analyzers are not unreasonable. If you acquire a spectrum analyzer and get to understand it you will wonder how you ever got along without one.

I'm about encouraging anybody with an interest to make as much of their own gear as they can. Start with easy and work your way up. I hope this gives you some ideas. Maybe brings up some more questions.

Don't forget a screwdriver and good selection of hammers <evil grin>.

73,

Bill KU8H

Gee Walt, I've ALWAYS used an MC-50 with my TS-830s Gold, from new in early 1980's. Always gotten fine audio reports. Still have mine, still works just fine.

Suggest an MC-50, if he can find one. High impedance, as you say.

CW is the only reliable means of measuring power output without a special peak holding meter.
The voice is a variable that makes it hard to see peak output readings without specialized meters and techniques.

Date: 2011-05-05 20:31:22 UTC
From: ki4ax
Topic: 31161 Message: 31161

On K4EAA's web page, Ken recommends to operate at 225ma plate current. There are others that recommend anything 200ma to 250ma is normal. Can anyone comment on what you think is a "safe" plate current for normal operation? My TS-520, when tuned up and operating in CW mode, is running 250ma according to the Ip meter setting on the rig. And can anyone suggest a way to reduce the plate current so that if it is too high or if I want to run a lower Ip current I know how to lower it.

Thanks

Dan KI4AX

They look nicer for a start!
They are easier to repair.
There are no menus to dig through.
They are every bit as sensitive as any radio needs to be on HF.
The PA section is almost bullet-proof. (Unless you are a complete fool.)

OK, mine has no IF shift - one would be useful.
I have to re-tune the PA and re-peak the drive after any substantial shift which can be a bit of a pain.

But I would never sell my 520 - it is my main digimode radio.
I'm sure it has a soul somewhere. (possibly in the VFO bit)

Thanks for your response. I think I've got most of the stuff you mentioned. So far I've collected a Simpson 260, an HP VTVM, a Heathkit IG-42 RF generator, and RLC bridge, a Tektronix's 475A "o" scope, a Heathkit TT-1 tube checker, a variac, and a Bird 43 wattmeter with the PEP mod. I've been wondering about a spectrum analyzer. They seem really expensive. Are there some older models that can be calibrated, and not cost a bar of gold?

On May 5, 2011, at 5:01 AM, Bill wrote:

> Hi Chris,
>
> I think I have your typos sorted out and you are asking about test/measurement gear for working on tube radios. Most hams have or can get a Digital Multi-Meter (DMM) almost anywhere for cheaps. Those usually have reasonably high input resistances on the voltage ranges but be careful about the maximum voltages. Our hybrids and many other transmitters have DC voltages approaching 1000 (one thousand) volts and more than a few transmitter tubes exceed 1000 volts. Your DMM won't be happy. The DMM is convenient for reading DC voltage levels in solid state circuits. The resistance ranges are also convenient.
>
> A vacuum tube voltmeter (VTVM) or it's FET equivalent will have a high input resistance (~10 MOhms) and you should get one with the old style analog meter movement. Most VTVMs and some FET VMs have voltage ranges up to 1000 or 1500 volts. That needle swinging upscale and then back down as you are tuning a stage for a peak (or dip) is much easier to use than any winking, blinking DMM. Used VTVMs in working condition are not expensive. The V-O-Ms with analog meter movements are *NOT* in the same class.
>
> For transmitters you really can't get around having some kind of RF wattmeter with decent calibration. One that will handle the power levels you expect from your radios. We are amateurs and we don't really need lab grade gear but the better accuracy you can get the better your results. Don't obsess over decimal points at the 100 watt level. I have some Bird wattmeters here and a military unit as well. Most of the time I use a small wattmeter/swr bridge that was intended for CB use. It has a 10 watt range and a 100 watt range (even though CBs are not supposed to put out more than 4 watts). There are internal pots for "calibration". The scales are not linear but logrithmic to read directly in watts. I used a HP scope to set the two scales. Such wattmeters can be home built or found at flea markets..holding down the expense.
>
> My HP scope runs flat up to 75 MHz and there are others in the HP and Tektronix lineup that are inexpensive and will run flat up to 150 MHz or higher. If you want to look at digital and HF signals you want one that will go into the VHF spectrum like that. Older publications suggest you can get by without a scope but those were written when any useable scope would cost you a years wages (or maybe 10 years). A picture is worth a thousand words!

>
> You can make sweep signal generators and wobbulators. There is a lot of info on the internet about those. For filter alignment you'll want one that is solidly built and reasonably stable. That 500 kHz wide I.F. "bandpass" filter in the hybrids demands a sweeper. Lucky for us that circuit doesn't need tweaking very much. The Heathkit type signal generators are maybe okay. In my experience the tuning rate is way to fast, they drift muchly, and output levels are not very well calibrated. Some of the mil surplus signal generators might be a better choice (I do have some Heath units). You can build your own signal generators, too, maybe based on a Heathkit.
>
> There are lots of other toys but the meters and a scope will get you off to a good start AND they will help you build other tools. Homebrew spectrum analyzers are not unreasonable. If you acquire a spectrum analyzer and get to understand it you will wonder how you ever got along without one.
>
> I'm about encouraging anybody with an interest to make as much of their own gear as they can. Start with easy and work your way up. I hope this gives you some ideas. Maybe brings up some more questions.

From: John Davidson
Topic: 31161 Message: 31166

I have been running my TS520 for almost 40 years without damaging anything in it. turned down the carrier control
I always tune for 200 MA of plate current. I get 100 W output.
For less power I detune the loading capacitor counterclockwise and re dip the plate until I get the power I want.
For lower power I also have also reduced the carrier control and minimum is about 3/4 Watt. (this only applied to CW operation)./..

Subject: [TS-520_820_530_830] TS-520 Plate Current

On K4EAA's web page, Ken recommends to operate at 225ma plate current. There are others that recommend anything 200ma to 250ma is normal. Can anyone comment on what you think is a "safe" plate current for normal operation? My TS-520, when tuned up and operating in CW mode, is running 250ma according to the Ip meter setting on the rig. And can anyone suggest a way to reduce the plate current so that if it is too high or if I want to run a lower Ip current I know how to lower it.

Thanks

Dan KI4AX

Dan:

First, I assume that by Plate Current you mean the measurement after you have peaked the Drive and Antenna Load controls and dipped the Plate current to maximize output.

My TS-520, operating in CW mode into a dummy load through an antenna tuner, puts out a max of about 95W with an SWR of 1:1.5 on 10 meters. At that point plate current is about 240 ma.

As for what plate current to use, employ you own judgement. It is a simple matter to reduce CW power output by turning the "CAR" control to the left to get whatever level below 100W you wish.

Note that the CAR control does not affect SSB output. To reduce SSB output you turn the "MIC" control , the Mike Gain Control, to the left. Now, the only way to read RF power output in SSB mode is to inject an audio signal at a constant level into the mike input, such as a 1000 hZ tone from an sudio signal generator, and read the output then.
If you cannot get below a certain power level by adjusting the MIC control that means your transmitter needs adjustment, as my TS-820S required.

Hi Kent,

Brian VK5BC was active on HF yesterday but I can't find any record of
him being on 20m. Maybe you got BZ (Bee Zee) and BC (Bee Cee) mixed
up? In any case hang in there because it look like the solar cycle is
heading up hill again and conditions will improve and I'm sure he
won't be the last Aussie you work.

Another audio improvement has to do with the speaker.

I stumbled onto a great improvement (At least to my aging ears). Both my 830 and 530SP are a bit bassy, but when I plug in a set of amplified speakers made by Harmon Kardon (HK 206) for personal computer use , I find a much crisper, less bassy, easier to copy audio.

As Walt says, try out what's laying around the shack.

Dave
KG4MGB

---- Walter Breining <n9wb@...> wrote:

==========
This change slightly raises the high frequency audio limit and makes the radio be slightly more full and less pinched. I think that this change would slightly benefit almost any voice. It will help some but I do not think that it will totally solve your problem.

If your mike is not an MC35-S it is the wrong impedance for a TS 830.
The MC 35-S is high impedance and is the correct match for your radio but the MC-35 that is not the S model is 500 ohms and will be a bit weak on your radio.

Even the MC 35-S is probably not the best choice for your radio. Heil sound can provide you with a good sounding mike for your voice. Be sure to tell them what radio you have and your problem with a bassy or muffled sound.

There are other solutions. A Astatic D-104 will be higher pitched. A non amplified one will be extremely higher pitched on your radio. It may sound too high or thin. A D-104 on a amplified stand will still be higher pitched but not as much. A D-104 with the FET mod that is in the files section of this group will be flatter yet but still have lots of articulation. If you do go with an amplified D-104, use the TUG-8 stand and not the TUG-9 stand. The TUG-9 stand does not work as well although it can be modified to act like the TUG-8. It is a bit of work to do.

A Shure 444 or a Shure 444D will have a higher response than the MC-35 and may be a good choice. The best choice of the two probably would be the 444 that is not the D model. It is high impedance only. The 444D is dual impedance and seems a bit flatter. The D model should be run on high impedance with your Kenwood.

Some of the very old Shure mikes, both desk and hand mikes from the 60s were ceramic and were high impedance. Ceramic mikes have a great deal of high frequency rise. Not all ceramic mikes were high impedance but most were. These were used on very olde CB rigs especially tube type, and commercial two way radios. Some very early PA paging mikes were also of this type.

Last but not least, if your MC-35 is the S model, try placing a .02 microfarad capacitor in series with the live mike audio lead. As a temporary test that can be done at the plug.

This will drop the level a bit so you will need to increase the mike gain.

I doubt if the MC-50 or MC-60 will help much but if you can borrow one, try it. It should be set for high impedance. Note that some of the MC-60 mikes had a wiring error inside of the mike itself. This results in weird sounds, RF problems, and bad audio, particularly with the pre amp on. It can be fixed, contact me if you run into this. The schematic on the MC-60 instruction sheet was also in error. Not all MC-60 mikes had this problem and it was more frequent in the MC-60 A. The MC-50 did not have this problem.

Grab mikes that are laying around and try them. I knew a ham that had fantastic audio and he was always asked what mike he used. It was a early 1960 vintage curled cord PTT, Lafayette Radio Ceramic hand mike that sold for $12.50 US new and came on an olde Lafayette HE-20C CB radio.

Subject: [TS-520_820_530_830] Audio Improvement in TS830S

Hi all,

I am a new TS830 owner , I have a bassy voice and audio with the microphone MC35 is muffled, I saw that there was a change in the files of this group to improve the audio by changing C106 (.015-microfarad) IF unit with a new .001-microfarad capacitor.
Someone he made the change and is it effective ?

Many thanks

Ah Yes, using the ol' stereo system on the HF rig trick! It's always worked for me, even when using it on my CB radio back in the day (and we've all used CB at 1 time or another). I've always agreed with Walt too.

I stumbled onto a great improvement (At least to my aging ears). Both my 830 and 530SP are a bit bassy, but when I plug in a set of amplified speakers made by Harmon Kardon (HK 206) for personal computer use , I find a much crisper, less bassy, easier to copy audio.

As Walt says, try out what's laying around the shack.

This change slightly raises the high frequency audio limit and makes the radio be slightly more full and less pinched. I think that this change would slightly benefit almost any voice. It will help some but I do not think that it will totally solve your problem.

If your mike is not an MC35-S it is the wrong impedance for a TS 830.

The MC 35-S is high impedance and is the correct match for your radio but the MC-35 that is not the S model is 500 ohms and will be a bit weak on your radio.

Even the MC 35-S is probably not the best choice for your radio. Heil sound can provide you with a good sounding mike for your voice. Be sure to tell them what radio you have and your problem with a bassy or muffled sound.

There are other solutions. A Astatic D-104 will be higher pitched. A non amplified one will be extremely higher pitched on your radio. It may sound too high or thin. A D-104 on a amplified stand will still be higher pitched but not as much. A D-104 with the FET mod that is in the files section of this group will be flatter yet but still have lots of articulation. If you do go with an amplified D-104, use the TUG-8 stand and not the TUG-9 stand. The TUG-9 stand does not work as well although it can be modified to act like the TUG-8. It is a bit of work to do.

A Shure 444 or a Shure 444D will have a higher response than the MC-35 and may be a good choice. The best choice of the two probably would be the 444 that is not the D model. It is high impedance only. The 444D is dual impedance and seems a bit flatter. The D model should be run on high impedance with your Kenwood.

Some of the very old Shure mikes, both desk and hand mikes from the 60s were ceramic and were high impedance. Ceramic mikes have a great deal of high frequency rise. Not all ceramic mikes were high impedance but most were. These were used on very olde CB rigs especially tube type, and commercial two way radios. Some very early PA paging mikes were also of this type.

Last but not least, if your MC-35 is the S model, try placing a .02 microfarad capacitor in series with the live mike audio lead. As a temporary test that can be done at the plug. This will drop the level a bit so you will need to increase the mike gain.

I doubt if the MC-50 or MC-60 will help much but if you can borrow one, try it. It should be set for high impedance. Note that some of the MC-60 mikes had a wiring error inside of the mike itself. This results in weird sounds, RF problems, and bad audio, particularly with the pre amp on. It can be fixed, contact me if you run into this. The schematic on the MC-60 instruction sheet was also in error. Not all MC-60 mikes had this problem and it was more frequent in the MC-60 A. The MC-50 did not have this problem.

Grab mikes that are laying around and try them. I knew a ham that had fantastic audio and he was always asked what mike he used. It was a early 1960 vintage curled cord PTT, Lafayette Radio Ceramic hand mike that sold for $12.50 US new and came on an olde Lafayette HE-20C CB radio.

Subject: [TS-520_820_530_830] Audio Improvement in TS830S

Hi all,

I am a new TS830 owner , I have a bassy voice and audio with the microphone MC35 is muffled, I saw that there was a change in the files of this group to improve the audio by changing C106 (.015-microfarad) IF unit with a new .001-microfarad capacitor.

Someone he made the change and is it effective ?

Many thanks

As we grow older our hearing ability change as well. Too often, we ignore our loss of being able hear the higher frequency as normal.
For those of us who grew up in the country, do you still hear the buzz of a Mosquito any more?
In most cases it is not our equipment, but rather our ability to hear the higher frequency as we grow older.

Don't use the LOAD control to reduce power on CW - that is simply putting the PA out of tune.

Tune up properly and use the CAR control to reduce power to the desired level. That's what it's there for.

My own ideas on CW use are to set the bias to about 10mA (just enough to bias the PA into conduction so as to eliminate key-clicks, which it does) then after correctly tuning the PA, set the operating plate current to 100mA. This should be more than ample for CW contacts, plus the PA will 'last forever' operating at this level of bias and drive - minimal heat being generated.

I have actually set the bias control on mine to minimum, reading zero on the meter (class C??) and still not detected key-clicks on a monitoring receiver, but I'm suggesting 10mA just to be on the safe side as other rigs may differ slightly from mine. Pesonally, I delight in knowing those old valves are getting an easy ride when operated that way.

If you hook up for a "direct" or + keying it will produce a steady key-down condition. "Grid block" or - keying is how all the Kenwood hybrids work.

I have my MFJ Grandmaster keyer outputs connected to A TS440s with the + connection and to my TS520 with the grid block connection. I just turn on the VOX on the rig I want to transmit on.

From: w5rkl
Topic: 31177 Message: 31180

CW keying in ALL of the hybrids including the T599, TS-510, is "grid block".

Grid block keying is just what the term means. A "negative" bias voltage is applied to the stage being keying, typically the grid of the tube being keyed, to "cut off" that stage when the key is not pressed. This prevents the keyed stage from conducting, essentially "opening" the signal path. When the key is pressed, the grid block bias voltage drops to a level that turns the keyed stage "ON", restoring the signal path, allowing RF to pass/be amplified by the following stage(s).

Most, not all, vintage transmitters use Grid block keying, as do most modern day transceiver. Solid state grid block keying does the same keying process as older tube based grid block keying does except with lower voltages.

Direct, or cathode keying, is a method of keying that, when the CW key is not pressed, the cathode of the stage(s) being keyed is held "above" ground, turning the keyed stage "OFF", opening the signal path which stops the flow of electrons in the tube. When the key is pressed, the cathode is at ground potential, allowing electrons to flow in the tube which restores the signal path, allowing the RF signal to be amplified and sent to the antenna.

A couple of example of "direct" or "cathode" keying are the Heathkit DX-20, DX-35, DX-40, DX-60 transmitters along with the Knightkit T-60, and T-150 transmitters.

31181. Replacing CB crystals - easily

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-05-07 23:08:15 UTC
From: Lou Blasco
Topic: 31181 Message: 31181

Hi All,

I had to replace the 29MHz band crystal (X8) in my TS520S. A previous owner had replaced the original crystal with one to suit the 27MHz band. As luck would have it the crystal is right underneath the band switch and probably the most difficult one of the lot to access. Looking at the board layout and the service manual it seemed to me that it's quite a job to remove the OSC COIL board just to replace the crystal.

I decided to try and replace the crystal without removing the OSC COIL board and found a method that seems easier than the one suggested in the service manual.

I removed the metal shield next to the OSC COIL board and disconnected the shaft coupler for the band switch then pulled the shaft forward until I could get to the solder connections on the OSC COIL board. ** Make sure you don't rotate any of the switch wafers** I un-soldered the old crystal and pushed the pins through until the crystal was free of the board.

I cut a small piece of heatshrink to go around the new crystal. Under the heatshrink I stuck a few inches of tinned copper wire that I bent in an "L" shape to allow me to feed the crystal under the band switch and poke it's wires through the board. It took about three minutes to get the new crystal soldered in place. Once the crystal was soldered in place all I had to do was slide the wire out from under the heatshrink and the job was done. The heatshrink remained on the crystal but it's so small you can't even see it under the band switch. I pushed the band switch shaft back in and replaced the shield and the hard work was done.

After a coil pack adjustment the radio is as good as new and I'm really happy with the results.

Thanks for the quick answer guys! Now all I have to do is hook up the cables and start back working cw! (as soon as I get up the guts to hit the key) And thanks for the explanation Mike. Now I understand how it works and the difference between the two.

According to the "Instruction Manual" for the TS-520SE under section 6.9 TRANSMITTER NEUTRALIZATION the procedure says to:

"Tune up the TS-520SE into a 50 ohm dummy load at 28.5 Mhz for CW operation as described in Section 4. Set the SG switch to off (down) and place a sensitive RF voltmeter across the dummy load. Flip the stand-by switch to SEND and adjust TC1 (reached through the adjustment hole in the top of the final section) for a minimum reading on the voltmeter. After the final section is neutralized, flip the stand-by switch to
REC and slide the SG switch on. "

"A good receiver tuned to 28.5 Mhz works very well for neutralizing if an RF voltmeter is not available. Instead of tuning for minimum voltage, tune for a minimum S-meter reading"

Which leads me to some questions about Transmitter Neutralization ? First, my Heath Kit "Cantenna" dummy load has a female RCA connector on the top near the coax connector. From the schematic printed on the side of the can it appears that this RCA connector is to provide "rectified" RF since it is fed through a diode. Isn't this basically the same thing as an "RF probe" for my voltmeter? And can't I use this point to take voltage readings with my DMM (non-rf type) for neutralization?

Also, I would like to get some feed back on using "a good receiver tuned to 28.5 Mhz" for neutralization? And can any one tell me why 28.5 Mhz? I am almost sure it has something to do with the reactivity of the Pi network but I would like to know a little more.

Lastly, is it safe to assume that if this procedure is works for a 520SE that it would work for the earlier 520?

Thanks,

Dan KI4AX

Hi Dan

1. Yes you are correct your Heath Cantenna circuit is a classical "RF Probe" circuit. You can use it as you describe but it wont let you ensure minimum reading. The problem with using it is the germanium diode wont allow you to get down to the millivolt range due to approx .4 volt turn on. There are some RF probe circuits that use an Op amp that get down to around 50mv and are used for qrp work that you could homebrew. Check K5NNA.

2. You really want to use an analog meter and not your DMM. Any time you are trying to peak or minimize a measured parameter an analog meter is better to allow you to see the peak or minimum.

3. Essentially your 6146s are high gain tubes and you are neutralizing them so they amplify and not oscillate. You typically neutralize on the highest operating frequency and neutralizing is really only good for one band and narrow frequency range. If you are not

going to operate on 10 meters there is no reason why you cant neutralize on 15 meters. When you get down to 40 and 80 not likely that you would need to neutralize.

4.For a good understanding of tube geometry and grid driven finals and why and how to neutralize them take a look at the "white paper" that Tom W8JI has on his website.

5.It is difficult for a ham who doesnt have test equipment or another receiver to perform neutralization as described in the manual. I am fortunate to have a 100 mhz O-scope(you can get by with 20mhz)and a Boonton RV millivolt meter on on my service bench. I enjoy helping local ham with this procedure.

6. Another method which is trial and error is to make small adjustment on the neutralizing capacitor and then see if peak RF output occurs at tank circuit plate current dip. I dont recommend this method unless you have no other way to do it. It requires a lot of key down time and I havent found it to be very easy or accurate. Lots of tweaks.

7. Maybe you can find an elmer or club member who will let you bring your 520 to his shack and use his test equipment? Short of that take a look at K5NNA accuprobe.

8. Last and most important use an insulated tuning tool that is substantial enough to adjust the neutralizing capacitor. You are coupling energy back from the Plate of the tube and there is full anode voltage present. High voltage and plate current can be a lethal combination. Not to scare you, but you must be aware of the hazard and apply sound, safe work practice to work with it.

Good luck
Terry K9TW

Dan, I'd say the output on your Cantenna should work fine, as long as there is enough RF to register.

The problem being that the Cantenna output is for taking measurements of 'real' RF, whereas when neutralising the PA, the amount of RF is minute, even less when properly adjusted - just leakage.

You can use a remote receiver for this, as it responds to the tiny bit of RF that does escape, just make sure you adjust the cap with a fully plastic tool - not just for safety, but also if it contains any metal this may act as a {poor} antenna and cause the receiver to detect varying levels of RF - you would be looking for a minimum S-meter indication indicating you had cancelled RF leakage in the PA as best as can be done.

28.5MHz, the high end of the rig's frequency range, is where neutralisation is at its most critical, and therefore the easiest to adjust for a null, or near null - this is why it is recommended.

Finally, yes, all the Kenwood hybrids can be adjusted in a similar manner.

I tried using 28.5 mhz on my 820S, and as soon as I used it on the lower bands it would just take off and blow the 115V line fuse. I ended up adjusting for a low reading balanced between 20 & 17 meters, which solved that problem. It now operates great on all HF bands. Also the plate current reads about 220 ma at 95 watts or better on my Bird.

28.5 is not cast in stone, every rig is different.

Good luck..David

Dan:

Kenwood's revised procedure for neutralizing the finals on the TS-820 is to:

1. Tune the rig up for normal RF output in CW Mode on 21.3 MHZ.
2. Turn off SG switch.
3. Put the output into a dummy load with a "T" in the Coax going to a suitable oscilloscope and adjust the neutalization capacitor for minimum voltage.

This should work just as well on a TS-520. I have have done this on my TS-820S and really ought to do it on my TS-520 as well, even though I have not changed the finals.

You need to make yourself a suitable adjustment tool using a wooden dowel shaped properly and dipped in varnish.

I you want to bring your rig over here to the East coast of Florida I will do it for you.

Thanks everyone for your replies on my post about neutralization. Terry, I'd like to ask what model of Boonton RF voltmeter do you have? I have a Boonton also that I have been wanting to get working. It has a loose wire that I can not figure out where it goes back to and I can not find a schematic for it either. If I can get it going this would be a nice addition to my bench equipment. Perhaps if you have the same model you can help me figure it out.

Anyway, the posts are very informative and have answered my questions. I have a new set of final tubes that I have had since I bought the rig but I am not quite ready to change them yet. I just want to make sure that when I get ready to do the job I have as much information as possible. By the way the tubed are performing right now I think I will leave them be. I am still on the original set of tubes and I am getting about 95-100w out of them on 20 and 15 meters.

All comments are welcome.....

Thanks again....

Dan--I have a very nice Model 92E. Boonton manuals and schematics are usually available on line. You will also need the RF probe for your Boonton. If you have problem finding a schematic let me know I can send you a copy of mine. Yes-would be good to get yours working as it is a very useful piece of test equipment for troubleshooting and alignment of your rig. If you are getting 95 to 100 watts out on 20 & 15 mtrs I wouldnt worry about changing your finals. If you do install the new ones make sure to set the resting plate current (50 to 60 ma). I normally place my scope or boonton across my Cantenna . If you dont have a uhf tee adapter to place on your Cantenna you can solder a 47 ohm resistor or a couple 100 ohm resistors in parallel to a PL-259 connector and screw it on your SO-239 on rear of rig and place your Boonton across this "dummy load" resistor to see your null reading. Make sure you have Screen Grid switch off. 73s Terry

Topic: 31195 Message: 31195

Hi all.Can anyone tell me if its possible and if so how to reduce the power out on my 520SE.I would like to use it for data modes at 20-30 watts.Thanks for looking.73..Jes - m0jsw

31196. Re: Transmitter Neutralization

Terry, I have a "Boonton Model 91H Sensitive RF Voltmeter." I was hoping it was the same model as you have. Any way if you can direct me to a schematic I sure would appreciate it. The one I have needs some cosmetic work but looks pretty good on the inside. Looks like it might have been military surplus at one time.

Thanks

Dan KI4AX

I use mine exclusively for digital: Simply use the mic gain control - ensure it is pushed in as you do not want the processor operating.

Carefully adjust the mic gain until you get the desired output, but be aware that if you change frequency on the waterfall, the output will probably change quite a bit (it does on mine) so after changing waterfall position have your hand on the mic control ready to back it off or up as the case may be. This variation in level is caused by variations in the filter responses, and may possibly be unique to my rig, but be prepared for it anyhow.

I'd say don't operate with more than about 100mA plate current either, as otherwise the tubes may averheat - remember that digital modes are continuous output, not intermittent as is voice or CW.

Have fun! :)

Dan--I believe the military version of your meter is the URM-145? I am not sure. You can Google on this Model number and find manuals and schematics. I did a quick search on Boonton 91H and didnt find any free manuals or schematics. A search on URM-145 yields more results. Try this site..... www.tpub.com/content/electronicmeters/TM-11-6625-524-15-1/ There is a guy over on QRZ K2ERG who is also looking for service information for his 91H. You might want to email him and share info. 73s Terry

I have a TS520S , I use a circuit from MODS DK.
It applies a negitive voltage acress the ALC circuit (via a 9volt battery &
250K ohm variable pot) ,This allows me to adjust output from 100watts to a
milliwatt.
T
the circuit and another similiar is in the FILES section of the group.

I do not know if it will suit the 520SE but I believe that for the low cost it
would be worth a test, YES IF YOU CHANGE FREQUENCY YOU WILL NEED TO ADJUST THE
SETTING ON THE VARIABLE CAP.

Adjusting the "carrier" control only works for reducing power on CW.
That's how I run low power CW on my TS520.

.....

I have a 530SP and it may be different. I won't opine on the suggestion
above, but I would just turn the CAR (carrier) down on mine.

There isn't anything mysterious about the 2 battery powered circuits. Either one with work with all of the hybrids.

Whether one chooses to use the 2 component battery and pot circuit or the battery powered transistor circuit is entirely up to the individual. They both do the same thing, control the IF Unit's 8Mhz "TIF" signal level that is applied to the RF Unit!

The only operational difference between the 2 circuits is the transistor circuit is a bit more linear than the pot and battery circuit is.

Greetings people,

Anyone know if Ken K4EAA is OK? Have sent him several emails over last month and have not received anything back

Regards,

Dave

Dave,

As per what Mike said...Ken is REAL busy...he accepted a rig of mine for a repair that I could not handle. He has had it since the first week of February 2011 and, has not been able to get to it yet. He...believe it or not...does other stuff...hihi.....

I like the idea of a Kenwood hybrid net - I bet it could become popular.

The only question is what band?? I know a lot of you are in the USA so even 40m seems a bit dodgy, although not impossible. 20m would be impractical if the net were during the evenings.

So - on balance I suggest 40m.

When your 820 has been operating perfectly and all of a sudden the frequency readout goes blank and you cannot transmit I have some advice. At first sit and look at it trying to figure out what you might have done wrong. Go through the book and make sure all of the knobs, buttons etc are set correctly. Check the SG switch in back (you've done that before). Thne think depressing thoughts about how much time you are going to have to spend diagnosing the problem with little equipment and less knowledge. Hope that Mike or Gordon will come up with something easy that you can understand.

When you start to question why you invested in this old sure to fail technology you might want to make sure that the cable to the remote VFO hasn't come loose. How happy you will be when you plug it back in and all is well!! So far every fault with my station has been self-induced.

Rick -

As John pointed out, reducing the carrier _only_ works on CW. Since digital modes use SSB, reducing the carrier level will not reduce output. The mic gain needs to be reduced or either of the suggested circuits can be used to reduce output via ALC.

I find that 40M does not get you more than 500 miles at night running 100W and far less than that in the daytime.

20M seems much better and has been open at night quite a bit lately.

Of course I have talked from the east coast of Florida to Tucson, AZ on 10M but it is rather spotty.

Nope! I've done it with mine and there's absolutely no problem with doing that. As in all modes, remember to always keep watch of the plate current...that's your key to know what the tubes are doing.

BTW, I don't know if it was mentioned on this thread, but you can always just use a 9v battery and a 10K pot connected to the ALC input to reduce the output power. Need a schematic of that?

Yes, also I would like to know if somebody has connected this ALC control in the ts-830 and How, as far as I know the back DIN connector in TS-520 an 830 have different pin connections.
I remember that the TS-830 remote connector (the one that has the ALC input) does not have ground pin, isn't it? so you have to get a ground or maybe use pin 7 which is not used to bring a ground to the external battery and pot just to use a male Din and not have cables around.

31234. Hybrid Net

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-05-12 01:11:50 UTC
From: ki4ax
Topic: 31234 Message: 31234

I would also be interested in a Hybrid Net. I think the band that is used should be determined by the time of the net. 20 meters would be better suited for daytime and I would think 40 would be better for night time or early morning. There is almost always some propagation on 20 meters in the day time.

Dan KI4AX

31235. Re: Hybrid Net

Topic: 31234 Message: 31235

I sometimes participate in the 3905 Net on 40 in the late day/evening and on average it seems to work well. I am new enough to the hobby however to only know enough to be dangerous. I think this is a splendid idea.

Topic: 3727 Message: 31236

I just finished repairing a "It worked when I last used it" Ebay 220 station monitor. Is there a reason that I want to install it just after the exciter to monitor the exciter SSB signal versus installing it after my amp. to monitor both, the exciter when amp is not on and my final signal when the amp is on use?

How about Saturdays, 2 PM Eastern (11 AM for us on the West Coast, in case the band is open and long)? What say 7.225 or 7.250? There is a ham swap net out here on 7.240 at 12:30 local Pacific Time (3:30 EST).
Thanks in advance.

OK.....NOW THAT WE SEEM TO HAVE A GOOD NUMBER OF PEOPLE FOR A NET, AND IT SEEMS THAT MOST PEOPLE FEEL THAT 40 METERS IS THE BAND TO AT LEAST START ON, WHAT DAY OF THE WEEK AND TIME DO YOU GUYS THINK WOULD WORK FOR MOST MEMBERS OF THE GROUP WHO SHOWED INTEREST IN ORGANIZING AN ON AIR NET?

I would also be interested in a Kenwood Hybrids Net. I know one other person
who would be also. Count us in.

From: basketoak@cox.net
Topic: 31206 Message: 31241

From my QTH i n Virginia, 20 would be the only band to pull in 6/7 land.

I regularly hook up with the 14.300 Net which connects to sailing vessels from Long Beach, CA.

I suggest all check connectivity to that net and report back.

Unfortunately we may find that people in the mid west are too close to 6 land on 20, but we should try it.

40 mtrs would be fine after dark, or for an east coast regional net in day time.

Didn't we go through all this "net" stuff several years ago? Anyway, once a frequency/band/time/day is decided upon (which is not a trivial exercise), there needs to be at least one or two net control stations to control/guide the masses that gather, or within ten minutes, anarchy will prevail.

Topic: 31245 Message: 31245

Someone had told me that kenwood made an external Digital readout VFO that would fit my 820S ?
or do I have to use a model made for another model transciever?

I am also new to the group and will be getting my 820s tommorow!!
Already have a kenwood AT-200 tuner that I have been cleaning up and getting ready. Can't wait to play!
Ill prob use the ole 706MKII mostly for PSK31

Hi John,

There are no external VFO's with digital read out, made by Kenwood, that are compatible with the TS-820. The VFO you may have been mistakenly referred to is the VFO-230 which is not compatible with the TS-520 and/or the TS-820.

The only external VFOs that are "plug and play" compatible with the TS-520 and TS-820 are the VFO-520 and VFO-820. Both VFO-520 and VFO-820 are interchangeable between the 520 and 820 series transceivers.

Pete:

Yes you are absolutely right. My personal experience with nets is limited to that with an OK storm warning net, which required very tight net control and coordination between the meterologist, radar, and the stations, always mindful that what we said might go out over the TV in seconds and was being listened to by the public with "Police Band" radios. This is extreme compared to a typical ragchew net but you still do need tight control. I have yet to break into any of the typical ragchews going on on 40M because they are moving so fast that you can't get a word in and have no net control.

I think we will need at least 3 nets, one for East coast, one for Midwest and one for West coast, with a net control for each, and once we get them up and running we may be able to combine them. We may even need to go with an even more regional approach, such as 4 land, 5 land, 6 land, etc. and then expand from there. And there is nothing wrong with fairly local nets on 10M - Lord knows there is plenty of bandwidth for them!

Topic: 31248 Message: 31248

Hi gang--Thinking of buying some Deoxit F5 Fader Lube for cleaning scratchy pots (AF gain etc) on my TS-830s. Couple of questions:

1. Is the F5 a cleaner/lube or just a lube? Do you need to apply Deoxit D5 first and then the F5? Is there another brand that works as well?

2. How to you apply cleaner/lube to the pots? I dont really want to remove the front panel unless it is best way to do it. Is it possible to set rig on back (in styrofoam shipper) and remove knobs and apply cleaner to the shafts and let lube flow down into the controls? I am afraid this might remove any shaft grease that manufacturer used?

Looks like you can get spray tip extension in at an angle on most of the controls. Mode switch looks to be sealed unit?

Appreciate any suggestions that you have been successful with.

Yes, also I would like to know if somebody has connected this ALC
control in the ts-830 and How, as far as I know the back DIN connector
in TS-520 an 830 have different pin connections.
I remember that the TS-830 remote connector (the one that has the ALC
input) does not have ground pin, isn't it? so you have to get a ground
or maybe use pin 7 which is not used to bring a ground to the external
battery and pot just to use a male Din and not have cables around.

Terry,

1. DEOXIT D5 label says "More than just a cleaner." I have not used the F5. I pretty much use D5 exclusively...and nothing else. I am sure there are others that may work as well...just have not really use anything else for a number of years.

2. Turn off and unplug radio...especially if you plan on cleaning the rotary wafer switch in the final cage area. You are going to have to remove the top and bottom covers. The D5 has "L" "M" "H" on the top of the can...I use the "L" (less) use the wand and direct the spray into the pot/control... a little goes a long way.. and work back and forth numerous times...some caned air helps too.

3. Don't worry about the "shaft grease." some of that stuff has been in there for 20+ years...and a bit of cleaner can make them move a bit more easily(not so stiff) I do not use grease on other things...I use a fine tip oiler with synthetic lube with teflon...or "clock &watch" oil. The former is much cheaper.

Good Afternoon Group:

Based on recent exchanges, I sifted through my Kenwood related files to find the file referenced above. Turns out a bare-bones version is already in the file section (on line) as a simple schematic.

The file I uploaded is the same drawing with the addition of explanatory text. Perhaps a bit more helpful...

I guess it's a octal socket for some (mine is a TS-520SE with that), a DIN for others.

hi,

I also built one for my TS-530.

be sure to use the DIN 270 degree type.

Same DIN that was used on the famous
Commodore 64 family of computers.

Joe--Thanks for sharing your practice. I have cleaned the bandswitch wafers on the RF board and the S22 in the PA cage. I used Deoxit D5 and blew it off with canned air. I havent cleaned any pots yet. As I mentioned the AF gain is getting scratchy especially at the minimum end of travel. So I wanted to find out what others were using on the pots. I did use Tri-flow on the VFO gear train and light machine oil on fan bushing felts.

Terry,

1. DEOXIT D5 label says "More than just a cleaner." I have not used the F5. I pretty much use D5 exclusively...and nothing else. I am sure there are others that may work as well...just have not really use anything else for a number of years.

2. Turn off and unplug radio...especially if you plan on cleaning the rotary wafer switch in the final cage area. You are going to have to remove the top and

bottom covers. The D5 has "L" "M" "H" on the top of the can...I use the "L" (less) use the wand and direct the spray into the pot/control... a little goes a

long way.. and work back and forth numerous times...some caned air helps too.

3. Don't worry about the "shaft grease." some of that stuff has been in there for 20+ years...and a bit of cleaner can make them move a bit more easily(not so

stiff) I do not use grease on other things...I use a fine tip oiler with synthetic lube with teflon...or "clock &watch" oil. The former is much cheaper.

Ok, after sinkhole remediation has been performed on my house, I'm back at this 530! I have connected to an antenna, and there is no receive either. I thought the receiving end was ok since I could receive a marker signal. After checking my antenna connections, I can receive no psk signal on 20 meters which is usually hopping loud in the afternoon at my location. After a brief tune through the bands, nothing heard. So, my original thought that I could receive is false. After all that has been done, I have no receive and no transmit. The digital display is working, but no signal, in or out. Any ideas? thanks all for your previous posts and comments. 73 Steve

Subject: [TS-520_820_530_830] Cleaning Scratchy Pots

Hi gang--Thinking of buying some Deoxit F5 Fader Lube for cleaning scratchy pots

(AF gain etc) on my TS-830s. Couple of questions:

1. Is the F5 a cleaner/lube or just a lube? Do you need to apply Deoxit D5 first

and then the F5? Is there another brand that works as well?

2. How to you apply cleaner/lube to the pots? I dont really want to remove the front panel unless it is best way to do it. Is it possible to set rig on back (in styrofoam shipper) and remove knobs and apply cleaner to the shafts and let lube flow down into the controls? I am afraid this might remove any shaft grease

that manufacturer used?

Looks like you can get spray tip extension in at an angle on most of the controls. Mode switch looks to be sealed unit?

Appreciate any suggestions that you have been successful with.

Hi Bob,

The TS-520/820 series used the octal socket
and the TS-530/830 series used DIN 270 socket.

I built a qrp circuit for my ts-520 and ts-530.

I've had excellent results cleaning pots and faders on broadcast equipment, consumer electronics and ham gear with DeOxit D5 followed by F5. They sued to be DeOxit and Cali-Lube. Same product different names and work great. If a pot is noisy clean it first with DeOxit and follow with lube. To preserve quiet operation every now and then a drop or so of lube will keep pots working quite long. Good for selector switches, lever switches and other contacts also. Just be careful around phenolic wafer switches as the phenolic material will absorb the liquids. BTW I only use the liquid with the needle applicator and not the spray. Spray is a last resort when I cannot fit the needle applicator. Spray is messy......

Hi gang--Thinking of buying some Deoxit F5 Fader Lube for cleaning scratchy pots (AF gain etc) on my TS-830s. Couple of questions:

1. Is the F5 a cleaner/lube or just a lube? Do you need to apply Deoxit D5 first and then the F5? Is there another brand that works as well?

2. How to you apply cleaner/lube to the pots? I dont really want to remove the front panel unless it is best way to do it. Is it possible to set rig on back (in styrofoam shipper) and remove knobs and apply cleaner to the shafts and let lube flow down into the controls? I am afraid this might remove any shaft grease that manufacturer used?

Looks like you can get spray tip extension in at an angle on most of the controls. Mode switch looks to be sealed unit?

Appreciate any suggestions that you have been successful with.

I could do net control every once in a while. Like I said I am a NCS for omiss. Never thought about stations outside of the us. I am sure we can find something. Just remember you can please some of the people some of the time, but you can't please all people all of the time. I will be happy to help anyway possible.

I do some QRP with my TS520, turning the carrier level down to 5-20 W often.
A lot less than 100 mA plate current key down.
My tubes have lasted 20 years since last replacement.
Less plate current = less heat = longer life.

The problem with 20 M and higher is the long skip where closer stations never will hear each other.
40 is a good compromise where you will rarely have east and west coast hearing each other (well...at night they can) but everyone inbetween can hear each other. At least in the daytime hours.
 In winter the net can move to 80M when the band is open everywhere at night and there is little T-storm QRN.

Subject: [TS-520_820_530_830] Hybrid Net

I would also be interested in a Hybrid Net. I think the band that is used should be determined by the time of the net. 20 meters would be better suited for daytime and I would think 40 would be better for night time or early morning. There is almost always some propagation on 20 meters in the day time.

I think this might have been asked before but....
Those of you that are using the Kenwood external speakers, are they any good?
Do the Filters help at all?
Obviously I like the fact that they match the rigs and allow hooking up two rigs to one speaker but I want anyone using one of these to give me your opinion on wether or not those filters actually help the sound??
I have an 820 so I might try the matching speaker

Robin,

First check the value of the 4 20 ohm cathode resistors on the final board.....they should be close to 5 ohms to ground..the plate current metering is taken from these. You may be getting a "false" Ip if you are just using the front panel meter. Also, you may have a problem in the "final cage area," possibly L-1/C-7/C-8. These are suspect if you have good HV, good drive, and good finals. Power will usually fall into the 50-70 watt range. Check Ken Kemski's web site K4EAA.com regarding the "final cage repair." He has the parts too! good luck.................

Filters help...speaker is satisfactory...lots better than the transistor radio speaker on the top cover. I pretty much use good quality headphones.

Subject: [TS-520_820_530_830] Kenwood External speakers, are they good?

I think this might have been asked before but....
Those of you that are using the Kenwood external speakers, are they any good?
Do the Filters help at all?
Obviously I like the fact that they match the rigs and allow hooking up two rigs to one speaker but I want anyone using one of these to give me your opinion on wether or not those filters actually help the sound??
I have an 820 so I might try the matching speaker

If your 530 is indicating full power output with 800VDC HV at 225ma IP current after tune up then that's the normal 180 watts DC input power in CW mode for the 530.

The final amplifiers in all of the hybrids operate in Class AB1. The final amplifier's typical efficiency rating is 55% which means typical power output in CW mode will be 100 watts (180 - 45% - 99).

I agree, try another watt meter and compare the results between the 2 watt meters. Don't use sideband as the test mode, use CW.

Check the top plate cap on the 6146. This is the tab soldered to the top of the tube, not the slide on cap with the parasitic suppressor. If the cap is loose then power output will be affected. Don't waste you time and money on matched tubes. That's not the source of your problem, based on the information you have provided.

Replace the short length of coax cable between the 530 and the dummy load/watt meter with a known good cable. A bad solder connection in the coax cable may show up as a good DC (ohm meter) connection but when RF is applied, that so called "good DC" connection can present a high resistance to RF.

Don't assume anything, check everything even to the point of using other watt meter.

The important thing to remember about filters in speakers is, the filters are "audio filters" and will only filter the "audio" signal. Any signal that falls within the bandpass of the IF crystal filter can cause interference that can lead to significant reduction in the audio filter's output audio signal.

Selectivity in a receiver occurs at 2 stages

1. RF amplifier (antenna coils)

and

2. IF stage (crystal filters)

Skirts on crystal filters that do not have steep sides will allow signals to flow through which can result in interference. When this happens, especially if the interfering signal is quite strong, no amount of "audio filtering" will eliminate or significantly reduce the interfering signals.

Agreed. Sounds like the cathode resistors have risen in value, and
they should be
looked at after checking the obvious external pieces of the puzzle
(i.e. ensuring
your dummy load, coax jumpers, and trying a different power meter to eliminate
a possible issue there). Checking the screen voltage may also show
that the screen
resistors have risen in value as well.

The SP-820, which I'm addressing specifically since you mentioned that you had an 820 and were thinking about the matching speaker for it, is a very well built speaker and has a reasonably effective LC filter setup to cut high frequencies/low frequencies as advertised and enabling the operator to have a small degree of tone control in the received audio. Main use in my shack is to cut off the "high" highs to reduce listening fatigue.

If you're expecting DSP filtering or some form of active audio filtering in line with an Autek QF-1 style audio filter, you will not find that with the SP-820. The filters are simply there to provide a small degree of tone control as noted above. That's it.

Having said that, I have mine down stream from either an JPS NIR-10 or an Autek QF-1 and still find using the filters in the speaker help me with reducing the highs a bit which certainly cuts down on my listening fatigue. When using headphones, I plug them into the speaker's headphone jack to allow me to continue to use the speaker's filters for that purpose.

If you suspect the IP meter display is, in fact, in error, I recommend checking not only the cathode resistors but also R6 (2.7K 1/2 watt) and R10 (6.8K 1/2 watt) as well.

Having nothing on the agenda today I decided to take a look inside my TS-830S I bought about 6 months ago. While familiaring myself I saw a patch of electrical tape covering something apparently to keep it from shorting to the case. When I removed the tape I see several resistors soldered to the final unit board under one of the finals sockets. My copy of the owners manual and the service manual don't show the resistors or anything being there. The apparent addition looks newer than the other components, so I'm assuming it's a mod. I haven't had a boat anchor in a long long time and I'm really rusty so any consideration and patience in figuring this out would be appreciated.

I created an album N5YPJ here in the photos and posted a photo of what I am asking about. I don't see a way to insert it here in the message.

Hi Richard,

That is not factory!

I can't tell whether the resistors, all appear to be in parallel, are connected between the DRV terminal or pin "4" on the final tube socket and ground. I suspect they are connected between the final tube socket pin 4 and ground.

You need to remove all of those resistors then remove the "BLUE" and "WHITE" wires on the PC board. These wires are on the upper left and upper right corner of the picture. Then remove the PC board Phillips head mounting screws and gently pull the board out and look at the four 20 ohm 1/2 watt cathode resistors. More than likely they will be burnt open. If you find the 4 cathode resistors have been burnt open, replace them with new 20 ohm 1/2 watt resistors then install the board back into the 830 and reconnect the BLUE and WHITE wires to their pins and test the 830.

I agree with Mike.
Someone has put those resistors on the underside to make up for open R2
R3 R4 and R5
It appears the two Blue ones are two 10 ohm in series. Probably trying
to get the net result of everything in parallel close to 5 ohms
Remove them, remove the board and replace them with 20 ohm 1/2 watt
resistors. I generally only have to remove the Blue wire to get the
board to flip over.
It isn't hard to remove the screws to the board and gently flip it over
to see the resistors. Of course, you have to remove the tubes first :-)

Good luck and we are here to help

> I experienced very similar symptom with my TS-530SP. About 70 watts out @800v and 225ma. As Mike mentions if the silver anode cap on the tube has a poor connection to the plate lead that exits the tube you will have a high resistance connection there and you wont have 800V EP under load at that anode. You may find that silver cap pulls off the top of tube and is stuck in the plate connector when you attempt to remove it. They can be resoldered but the lead out of the glass envelope is typically very short. I had measured EP at top and bottom of the plate choke and it was good. I finally decided to try another set of finals and when I pulled the plate cap off the back tube it came off in my hand. I was holding the plastic plate cap, the parasitic suppressor and its accompanying lead that had pulled from the solder connection on top of the plate choke. Close look at the solder connection revealed a perfectly round hole that the suppressor lead could plug back in to. You couldnt see it when the lead was plugged back into the hole unless you looked real close. Only clue I should have noticed was the grey color of the solder joint. In short it was a cold solder connection. I reheated and applied a little more solder to both parasitic choke leads on top the plate choke. I now had 100+ watts output @ 225ma. This is not the first time I have had poor or missing soldering with connections inside the PA cage. Good luck. 73s Terry K9TW

We have a old gear net at 730 central time 3970. All old tube and hybrid rigs are welcome. For that matter everyone is welcome. Informal and we have a long comments section to the net. Net control is in TX and the band lengthens out by 8:00 pm.

I have no problem working from MI to TX on 80M with my old TS520 but it has been so long since I tuned it above about 3560 that I'm not sure the dial still goes up there .! :D

We have a old gear net at 730 central time 3970. All old tube and hybrid rigs are welcome. For that matter everyone is welcome. Informal and we have a long comments section to the net. Net control is in TX and the band lengthens out by 8:00 pm.

I should have been more clear. Mike guessed right at what I was trying to say. The 3905 Century Club is a net on several different bands
at different times. The 40 meter net can go coast to coast with some occasional DX on many nights. It starts around 5:30PM CST. I do better on it as it starts to get dark from MN. It is a great place to listen to many different operators in a short period of time.(well over 100 many nites) Many are very good operators and few not so much. I use it to develop technique.

I am assessing my location for a 40 meter antenna to get on the Hybrid Net. My first inclination would be to put up a dipole but due to trees, power lines, metal roof etc. this my not be practical. I'm trying to figure out how to put it up without getting too close to any of the above. I have an old TELEX Communication 18ATV/WB-A Vertical Radiator antenna that I believe is in usable condition. As many of you already know the 18ATV is a trapped vertical antenna which will work on the 10 thru 80 meter ham bands. I am wondering if anyone has used this type of antenna mounted above ground with out radials? I have used this antenna in the past while mounted at ground level and while I made contacts with it I remember it seemed pretty noisy and it did not get out too well. I am wondering if height will make a difference in its operation and whether I have to use radial or if I can get by without?

Thanks,

Dan KI4AX

From: Jim S
Topic: 31234 Message: 31298

Almost any of the older trapped vertical designs are 1/4 wavelength antennas. The MUST be operated either above ground with at least 3 radials per band to be effective, or on the ground with a suitable ground plane of several more radials (maybe as many as 120, although that is pretty rare in a ham installation) resonant on the lowest frequency of operation.

Trying to operate the antenna without radials is like trying to operate half a dipole. It just won't work !

RE ground mounting: Radials do NOT have to be straight. They can be zig-zagged in order to fit the area you have available. If you need to compromise, it is better to install several shorter ones, rather than a few longer ones.

Remember too, that a vertical is going to have different radiation characteristics than a horizontal. It is going to radiate more strongly toward the horizon and less so at higher angles. That will make it a better DX antenna, but performance will suffer stateside. All things to keep in mind.

Good luck! 73 , Jim AG3Y

I like the needle applicator best because it can be used anywhere without making a mess. Also look at the pen applicator for edge finger cleaning. An alternative is the needle applicator and a chamois tipped tape head cleaner. Q-Tips work also and both eliminate the cost of the pen applicator. At one time the pens contained a more highly concentrated solution, but I have not purchased any in several years since I use the tipped applicators and saturate the tip as needed with the needle applicator. Caig also sells tiny brushes that work great for cleaning socket connectors and are more firm than a pipe cleaner.

I've had excellent results cleaning pots and faders on broadcast equipment,

consumer electronics and ham gear with DeOxit D5 followed by F5. They sued to

be DeOxit and Cali-Lube. Same product different names and work great. If a pot

is noisy clean it first with DeOxit and follow with lube. To preserve quiet

operation every now and then a drop or so of lube will keep pots working quite

long. Good for selector switches, lever switches and other contacts also. Just

be careful around phenolic wafer switches as the phenolic material will absorb

the liquids. BTW I only use the liquid with the needle applicator and not the

spray. Spray is a last resort when I cannot fit the needle applicator. Spray is messy......

Hi gang--Thinking of buying some Deoxit F5 Fader Lube for cleaning scratchy pots (AF gain etc) on my TS-830s. Couple of questions:

1. Is the F5 a cleaner/lube or just a lube? Do you need to apply Deoxit D5 first and then the F5? Is there another brand that works as well?

2. How to you apply cleaner/lube to the pots? I dont really want to remove the front panel unless it is best way to do it. Is it possible to set rig on back (in styrofoam shipper) and remove knobs and apply cleaner to the shafts and let lube flow down into the controls? I am afraid this might remove any shaft grease that manufacturer used?

Looks like you can get spray tip extension in at an angle on most of the controls. Mode switch looks to be sealed unit?

Appreciate any suggestions that you have been successful with.

I seem to remember some "Q-Tip" type applicators that are made of a foam rubber substance, rather than cotton fibres. I would prefer them to Q-Tips simply because they would leave nothing behind if you used them to swab the edge of a circuit card. You can probably find them at your local drug store.

31301. patch coax cable types

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-05-14 17:10:46 UTC
From: ktwhy2003
Topic: 31301 Message: 31301

I'm wondering if for short patch cables, the type of coax used it very critical?

I've have my TS-830S set up a short time now (haven't used it much due to a lot of probs coming down on me right now)
and right now I'm using about 2 foot long RG-58 cable left over from the cb dayz many eons ago. It's seems to work fine, but I'm wondering if I should get a cable made with RG-8X or something else, and if it's make much of a difference for only a couple feet.

The coax going out to me antenna is RG-8X into a multi-bank mobile antenna on my apartment balcony, see http://radio.kentsoftware.com
That antenna will be replaced in time, it's on loan to me, from the same ham that loaned me his TS-50S to get me on HF (which I will be returning now that I was able to make the USS Yorktown special event contact today :)

thanks

Topic: 31301 Message: 31302

Some years ago, IIRC, Collins made some special jumper cables to run between their exciters (S line, etc.) and their 30L-1 Amp. I used a KWM-2 and a 30L-1 together, and never bothered with the special jumper, but maybe I was just lucky!

Since 2 feet is just a tiny fraction of a wavelength, even on 10 meters, I cannot imagine that there would be any difference at all between running 8X or 58, or even the smaller stuff, provided that it was rated for at least the voltage that the exciter put out. Most equipment rated at 100 watts or less should be quite happy with just about any cable, and the difference in losses between the various types would be almost un-detectable for that short a run.

However, as is always recommended, go for a good quality cable like Belden, since it has much better shielding characteristics, and is much less likely to cause problems like RF leakthrough (RF in the shack) etc.

I had some left over 1/4 inch superflex hard line for a jumper from my TS440s to an antenna selector switch and it got awkward if I had to move anything around.
 The "superflex" name is a misnomer.
 I went back to RG58 for my jumpers in the shack.
I use mostly RG8x for my long feedlines to antennas in the woods behind the house. The loss is not a factor because 'the antennas are used for 160-30M bands.

Who was it that suggested we use 15 meters for a Kenwood Hybrids net?

Maybe that is not a bad idea.

I just made my first two contacts ever on 15 Meters.

One was in Poland and the other one was in Germany. Good clear USB comm, too.

I was using with my TS-520 with a homemade dipole antenna located in my attic.

And I had thought I was doing quite well when I got Tucson on 10M a few weeks back.

Robert,

I was the one who suggested 15 M. Looking at 40 M would leave a lot of people out who would like to take part in the net. On 20 M we would have to find a hole and then communicate that to everyone. 15M has a lot of room and the band is coming alive and staying open into the evening hours. I am open to the majority as to what band we should try first.

Topic: 31206 Message: 31307

Pete et al.,

Yes, there were lots of net attempts a couple years ago, but lousy conditions finally won out. Hopefully that is changing for the better by now.

And as a side note, a separate Yahoo Group called "KenwoodQSO" was created to keep traffic about and for nets to a minimum on this group. Looks as though Walt N9WB and Ellen AF9J were/are sysops for the KenwoodQSO group and there are 77 members.

Do we have a consensus on the net? Is there a process by which we need to chose frequency, time, and control op? I would certainly enjoy talking with the others in this group and would participate in the net if the net's schedule permits.

Better late then never...

Don't see why not, hope you still have them both and you've since found the schematics.
I hope no-one thinks I'm spamming : got a 530 myself and saw an ad for the VFO-5.
But the output is 4.9~5.5 Mc (same as the 520's VFO)and I'd need 5.4~6.1.
Of course I could try to modify it, but it seems too much trouble for me.
Don't have a good F-meter or HF-voltmeter, and (temperature) stability would possibly also be a challenge.
And since I don't have the need for a second VFO I decided not to bother.
If my IF would be the same as the 520/510 however, I'd probably only need to change plugs.

Having nothing on the agenda today I decided to take a look inside my TS-830S I bought about 6 months ago. While familiaring myself I saw a patch of electrical tape covering something apparently to keep it from shorting to the case. When I removed the tape I see several resistors soldered to the final unit board under one of the finals sockets. My copy of the owners manual and the service manual don't show the resistors or anything being there. The apparent addition looks newer than the other components, so I'm assuming it's a mod. I haven't had a boat anchor in a long long time and I'm really rusty so any consideration and patience in figuring this out would be appreciated.

I created an album N5YPJ here in the photos and posted a photo of what I am asking about. I don't see a way to insert it here in the message.

Topic: 31313 Message: 31313

Hi,

I'm new to the group. Been a ham since 84 and now hold an extra license. After about a 13 year layoff I'm back or trying to get there, I sold all my equipment years ago, but have found and trying to purchase my first radio, TS 520, I purchased when I was 14.(very long time ago. A local ham bought it way back then and still has it. Been sitting up about 20 years.

It does have some problems but was surprised to find folks could restore the radio to original factory performance.

I'm very familiar with k4eaa. I have talked to him on email and spent much time on his site. But he is waaaay backed up, and it will be a long time before he can get to any other rigs.

Can any one comment on "old ham dave"-David Lyndon? He seems to know what he is talking about but don't have any references to go buy.
Anyone else out there that does this?
I'm looking for the full service option, cleaning, replacing, full alignment, etc....

Thank you

Who was it that suggested we use 15 meters for a Kenwood Hybrids net?

Maybe that is not a bad idea.

I just made my first two contacts ever on 15 Meters.

One was in Poland and the other one was in Germany. Good clear USB comm, too.

I was using with my TS-520 with a homemade dipole antenna located in my attic.

And I had thought I was doing quite well when I got Tucson on 10M a few weeks back.

Robert
WB5WSV

The problem with 15 or 10 M for a net is that you rarely hear anything closer than a thousand miles . you would not hear any check-ins except for local and VERY far.

I have to agree about being heard near and far. While we are on vacation right now in Washington State, I have been active but dont hear anything but the very close and Russia! I tried 20 and 40 but I tend to cause issues with our smoke detector(wired), and at 10 pm with two children under 5, and a wife trying to sleep that chirp just doesnt go over well here! (ah the good ol days before smoke detectors!, said sarcasticlly.

I hear a few nets on 15 but I am never able to hear all sides of the roundtable, this would be a huge problem as this would cause many of us to key up not knowing the others are presently on air. This has been a cause to me not being on 15 to often other then to listen, once home I can do things differently. 15 is great for contests and simple ragchewing otherwise I think!

my $2 worth,(inflation caused by children and marriage)

31320. Transmit has died

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-05-15 21:31:11 UTC
From: Chris Parnell
Topic: 31320 Message: 31320

Hi All,

Had my 830 working nicely until Saturday... for some reason I was struggling to get above 50W on tune up and then suddenly nothing out.
The HV reading is still there... looking through the final cage, I can see one of the tube filaments is light, but can't tell if the other is... I am suspecting not.

Just to clarify, I get no IP movement, no RF out and no ALC meter movement either.

Am I right in thinking the tube(s) are likely EOL?

Thanks
Chris, ZL1CDP

Hi Chris,
If one final is lite, the other must be too. The filaments are wired in series.
Check the resistors on the Rectifier board to see if any have gone up in value or opened.
What sort of IP were you showing at 50W out before nothing?

Gordon

Hello Brian,

Old ham Dave is a good guy, but I do not know how much he is involved with the restoration and repair or rigs any more. Drop him a line and find out. If you're willing to work around my work schedule (I'm a systems engineer/analyst on several radar projects for my "day job"), I'd be more than willing to do it for you. Everything electrical and most mechanical issues. The only thing I cannot take care of is painting. Again, the only thing with me is my work schedule. I am on tap for live fire testing of one of our radars in Arizona later this month (tentative scheduling dependent on range time). That, if it does come to be, would take a week and a half out of my possible time to do it. Beyond that, I look pretty free other than my usual M-F work week.

I had forgotten about Cliff. Cliff is a good one as well, and if
you're going to be down
in his neck of the woods, he used to offer drop off service if you
contacted him and
arranged it prior. Drop it off and then spend a few days in DFW, and
then go pick
up your rig.

Also of note, my offer wasn't intended to take away from the guys who do this as
their job. My offer was only extended in case Brian couldn't find
someone to do
the work on his rig due to their being back logged way into the
future. I do not
work on rigs as a job/profession, and never desire to take away from those who
do. For those of you who promptly emailed me (courteously), I wasn't nor do I
ever intend to do any such thing as taking business away from someone.

With that, I hope everyone had a great weekend, and got to enjoy some time
on the air even with the propagation gods being less than nice to us
here of late.

73 to all,
Jeramy W5XTL

Hi Gordon,

Originally... I was getting around 200mA for around 75w... then it dropped to around 50w at 200mA etc.

I have suspected the tubes were on their way out for a while - A friend of mine who helped with a repair said that he thought on one of the tubes was drawing more current than the other, as one was much hotter than the other.

Cheers
Chris

Chris,

Have you measured the final tube's screen voltage and compared the voltages between the two tubes? If not then I recommend you do that.

You can't tell how good a tube is working by simply feeling the bulb temperature. Voltage checks and comparisons between the two final tubes will tell you more about the final tubes than anything else you can do.

Hi Mike,

No I haven't measured anything yet (other than noticing that the HV meter on the 830 measures correctly).
I also do not have a spare set of tubes either at this point in time, but will do some measuring tonight when I get home.

Is it an easy measurement to do?

Thanks
Chris

Mike is probably on the right track. I have repaired many older radios and the resistor values do change over time. One Kenwood rig had the value of the screen dropping resistor doubled in value and the other one was open.

Hi Mel,

I have previously replaced the resistors in the final unit and regulator previously before I had an issue with the 830 about 3 months ago.
Will double check.

Cheers
Chris

Topic: 31320 Message: 31331

Hi all, a quick update.

Firstly I checked the resistors in the final unit and they were as follows (once removed)

R2 - 21.2 Ohms
R3 - No value
R4 - 20 Ohms
R5 - 21.2 Ohms

When I read the value in place, should be around 5 Ohms, they read around 7.4 Ohms.

Also R10 was high too... supposed to be 4.7K and was at 6.76K... so I will replace all of these and see if it solves my problem

One other thing I did notice though, which wouldn't have helped, I'm sure is that one tube is 6146B and the other is plane old 6146.

Cheers

31332. 3898 pecker

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-05-16 02:17:42 UTC
From: kevin
Topic: 31332 Message: 31332

I purchased a "pecker" to help me tune my amp without melting it from ignorance. I was trying it out on my 830. Basically you turn the VOX on, put the radio in SSB and then hit the switch on the pecker. You adjust the ALC to the far edge of the scale. (after you tune you put the ALC back where you would normally use it) My understanding is that it puts out a signal at a very low duty cycle which allows you to tune with no damage from tuning too long. They say that using a PEP wattmeter you can measure peak SSB.
Does anyone know why I get more wattage using CW than SSB using this method? (I understand about the peaks etc of SSB versus CW so maybe this is not a fair comparison.)What bothered me more was that there was that I got about 80 watts out on LSB and 50 on USB. (100 with CW. Why the difference between USB and LSB?

If the one or more of the 4 cathode resistor values changes, that results in a total parallel resistance change which affects the current through the tube plus the voltage drop that occurs across the cathode resistors which can affect the IP meter indication.

Since R3 is either burnt open or has changed to some significantly higher value, I recommend replacing all 4 of the cathode resistors. Don't assume it's okay to replace only R3 and that's good enough. The current through R2 through R5 in parallel changes as the total resistance changes.

R6 is part of the IP metering circuit and since R6 has changed values, i recommend changing both R6 and R10 with new resistors. Resistors R6 and R10 must be within the 2700 and 4700 ohm tolerance in order to ensure the IP meter display is as accurate as possible. Failure to take this into consideration can result in an inaccurate IP meter display.

While one 6146B and one 6146 may appear to cause the problem, the different tubes is most likely not the source of your problem.

There is very little difference between the 6146/6146A and 6146B. The only inter-electrode capacitance difference between the two tubes is as follows:

6146A
Grid #1 to Plate is 24pf maximum

6146B
Grid #1 to Plate is 22pf maximum

That's "2pf" difference which is not a significant difference to cause your problem, especially when operating in the HF spectrum.

The other inter-electrode capacitance values in the 6146/6146A and 6146b are the same.

Yes, I know the plate dissipation of the 6146B, as compared to the 6146/6146A, is much higher but when considering differences in inter-electrode capacitance between the 6146/6146A and 6146B, plate dissipation is irrelevant.

The 6146 and 6146A are identical tubes with the exception of the filament in the 6146A. The "A" filament has what is called a "Dark Filament". This means the "A" filament operates at a filament temperature of 350 degrees Kelvin below the filament temperature of the 6146. Other than that, there is, as I said, no difference between the 6146 and 6146A.

From: Chris Parnell
Topic: 31320 Message: 31335

Thanks Mike. Although I don't see the cathode resistors being the cause of the problem I am going to change them anyway (all)..

I have been and looked for replacements today but can only find 1/2w 20 ohm metal film (they are quite small)... or 1 watt 22 ohm carbon (slightly bigger physically than original ones).. I realise that physical size is not what's important here so I wonder what your thoughts are on either?

Cheers
Chris

> If the one or more of the 4 cathode resistor values changes, that results in a total parallel resistance change which affects the current through the tube plus the voltage drop that occurs across the cathode resistors which can affect the IP meter indication.
>
> Since R3 is either burnt open or has changed to some significantly higher value, I recommend replacing all 4 of the cathode resistors. Don't assume it's okay to replace only R3 and that's good enough. The current through R2 through R5 in parallel changes as the total resistance changes.
>
> R6 is part of the IP metering circuit and since R6 has changed values, i recommend changing both R6 and R10 with new resistors. Resistors R6 and R10 must be within the 2700 and 4700 ohm tolerance in order to ensure the IP meter display is as accurate as possible. Failure to take this into consideration can result in an inaccurate IP meter display.

> Yes, I know the plate dissipation of the 6146B, as compared to the 6146/6146A, is much higher but when considering differences in inter-electrode capacitance between the 6146/6146A and 6146B, plate dissipation is irrelevant.
>
> The 6146 and 6146A are identical tubes with the exception of the filament in the 6146A. The "A" filament has what is called a "Dark Filament". This means the "A" filament operates at a filament temperature of 350 degrees Kelvin below the filament temperature of the 6146. Other than that, there is, as I said, no difference between the 6146 and 6146A.

Hi Chris,

Mouser sells 20 ohm 1/2 watt metal oxide flame proof resistors for 15 cent each. Their part number is 660-MOS1/2CT52R200J.

The data sheet for the 20 ohm metal oxide flame proof resistors is

http://www.koaspeer.com/pdfs/res52.pdf

Vacuumtubes.net

http://www.vacuumtubes.net/Prices%206000%20to%207199.htm

sells 6146Bs for $32 each. I would replace both final tubes.

Once you have done those things, test the 830 for operation, tune into a dummy load.

73s
Mike
W5RKL

Hi Mike, Gordon and all.

OK... replacing the resistors in the final unit has enabled me to TX again - although I still only get 50W output (on an external meter). I am following the procedure to a T on the K4EAA website for tuning.
I replaced the R10 resistor in the final unit too, with a 10K resistor as per the schematic I have.... my IP reading is as follows:-

40Mts - IP around 160mA - delivers around 55W
20Mts - IP is around 160mA - delivers around 55W

Interestingly I can deliver more IP but less PO.

Any help to solve this problem would be greatly appreciated.
I have ordered a new set of valves but not sure this is the problem, I had a spare 6146 and now the TX (albeit low) is a lot more stable

Thanks
Chris, ZL1CDP

I was able to find it by doing a google search. For those that are interested, though, here is a link.

http://groups.yahoo.com/group/KenwoodQSO/

It appears that you will have to copy and paste the link into your address bar and hit go.

Perhaps some of us can set up a schedule to meet on the air. We could try different bands to see which one we get the best coverage with or something like that. I have an antenna that will resonate on 10 and 15 meters, already up, and I have been listening on 10 and 15 over the last few weeks. There is not much propagation on 10m (at least that I can hear). 15 meters opens some on most days but it is long stuff and usually best late in the day and early evening. I am in Florida and most of what I hear on 15m is Europe and West Coast USA.

I have a 20m wire up but I get a lot of TVI on that band so it is only open for me late at night until I can get the issue resolved. If we are going to do 40m I will take the 20m wire down and put up one cut for 40m. Or try a fan dipole or something like that. Any one had any luck with a multi-band dipole in the "fan" configuration?

Greetings group,

In the furtherance of my knowledge base...I need to ask a couple of questions regarding procedures in the service manuals(several models):

What can be used/ substituted for the 8 ohm "dummy load" used for several procedures.

Can a regular VTVM be used in place of an AF VTVM?

I am trying to become self sufficient as much as possible

I put up a hasty 20/30M fan dipole last fall just before winter it us.
It worked well enough that I recently straightened up the angles of the wires
and raised the feed point higher into the tree.
We finally had a few decent days where I could trim the wire for lower SWR in
the CW band on the 20M section..Good SWR on both bands below 1.5:1 now.

Joe: Most VTVMs will be reasonably accurate in the AF (20hz to 20Khz) frequency range. However, the problem you may encounter is that they may not go low enough in the mv range. For example, my Heath IM-18 VTVM has lowest range of 1.5 volts and the smallest graduated increment is 20 millivolts. This makes it very difficult to accurately read 5 millivolts or 6.3 millivolts as called out in the TS-830s service manual. My HP3400A True RMS Voltmeter on the other hand has 1 millivolt, 3 millivolt, and 10 millivolt full scale ranges that allow reading these lower millivolt levels very accurately. I also feel that a RF Millivolt meter is a must for performing many of the service manual alignment/calibration steps. You can slowly overtime assemble your service bench. A counter, scope, RF and AF millivolt meters, VTVM, Function generator, RF signal generator, dummy load, and wattmeter make up a pretty functional service bench for these old hybrids. Probably the most expensive item is the RF signal generator. You can get by with one of the old Heath or EICO generators we used in the old 455 IF can alignment days, but a HP8640b or similar is really the way to go. You dont really need a Spectrum Analyzer or Service Monitor. I have recently added Audio Spectrum Analyzer software to my lap top (Spectogram) and it is great fun to be able to see the filter passband and the effect of the VBT and IF shift. Just my opinion. Hi Terry,

Sorry... I meant Rectifier unit (not Regulator)....
My post was supposed to read that I replaced the resistors (R2,3,4 & 5) on the Final Unit and the main resistor on the rectifier unit (R14 from memory).

Cheers
Chris

31346. Value of R10 in the Final Unit - TS-830s

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-05-17 03:43:51 UTC
From: Chris Parnell
Topic: 31346 Message: 31346

Hi,

Not sure if it's been mentioned before, but I have a "downloaded" technical supplement for the TS-830s and the schematic of the final unit shows R10 at a value of 10K.
I have another schematic of the same final unit and it shows R10 as a 4.7K resistor???

Any ideas why? will it make much difference? I believe it's just for meter scaling purposes.

Cheers
Chris

Hi Butch, thanks....

I also did this, but in the service manual I have it doesn't state R`10 at all in the parts list.

It's as follows:-

Final Unit (X56-1380-00)

C1
C2
C11, 12
C13
PS1, 2
L1
L2
R2 - 5 (Solid 20 Ohm 1/2W)
R7, 8 (Solid 100 Ohm 1/2W)

And that's it... no value for R6 in the list and no value for R10.

Then as I mentioned I have two different schematics for the Final unit - one reads 10K the other reads 4.7K - Confusing, unless I am missing something really obvious.

Cheers
Chris

There is an R-10 in the Rectifier unit (X43-1370-00). Is that the one you're looking for?

C1
C2
C11, 12
C13
PS1, 2
L1
L2
R2 - 5 (Solid 20 Ohm 1/2W)
R7, 8 (Solid 100 Ohm 1/2W)

And that's it... no value for R6 in the list and no value for R10.

Then as I mentioned I have two different schematics for the Final unit - one reads 10K the other reads 4.7K - Confusing, unless I am missing something really obvious.

Cheers
Chris

Topic: 31346 Message: 31350

Most of the Final boards want 5 ohms to sample about 200 mA of plate current.

So they use 4, 20 ohm 1/2 watt resistors in parallel. The voltage produced would be 1 volt across 5 ohms at 200 mAmps

The metering voltage divider for the current sample is usually a series resistor of 2.7k with a 10k resistor to ground forming a 2/3 ratio. So the voltage going to the meter would be 0.75 volts.

Hi Butch, thanks....

I also did this, but in the service manual I have it doesn't state R`10 at all in the parts list.

It's as follows:-

Final Unit (X56-1380-00)

C1
C2
C11, 12
C13
PS1, 2
L1
L2
R2 - 5 (Solid 20 Ohm 1/2W)
R7, 8 (Solid 100 Ohm 1/2W)

And that's it... no value for R6 in the list and no value for R10.

Then as I mentioned I have two different schematics for the Final unit - one reads 10K the other reads 4.7K - Confusing, unless I am missing something really obvious.

Cheers
Chris

Thanks Philip,

Makes sense... I have put a 10K in there, but am getting a maximum of 50 / 60 Watts out and a maximum IP rating of around 160mA max for 50/60Watts out.

Cheers
Chris

There were three issued versions (-00, -10, and -20) of the TS-830S
service manual. The "-10" was mainly cosmetic/hardware changes but "-20"
had some component changes.

If you are uncertain if your Plate Current is accurate and what value your meter multiplier resistors should be you could use a DMM and read the voltage drop across your paralleled cathode resistors. My schematic shows 1.36vdc drop across the 5 ohms at key down which equates to 270ma which includes about 6 ma of screen grid current. So max plate current would be around 265 ma. My operating manual says to load to max of 265 ma (which I never do). So the 1.36 volt drop across the cathode resistors would be a good reading to verify your meter voltage divider is accurate. Assuming you have set the ALC to max in TUNE, the idle current in SSB mode (keyed) is on the order of 50-60 mAmps,

My experience with these hybrids using a good 12BY7A driver and good 6146 finals is that with the CW (constant carrier) output into a dummy load is 55-60 Watts at an Ip reading of 200 mA (using the CARRIER control) and with the plate dipped properly. Pushing the plate current any higher may result in blowing the 6 amp fuse.

Now in SSB modes with a properly tuned rig, the PEP will be about 120 Watts with a peak reading Wattmeter, which is about the max you can expect from these rigs. Of course, this will depend greatly on the mike gain setting and or compression. IMHO, 5db compression is the max one should use on these rigs, or you will negate the audio quality typical of Kenwood rigs.

If you drive a linear with these rigs, you will need an ALC negative voltage bias control or an attenuator, or you will beat the linear's grids to death.

For sampling the HV supply volatges, I use a BK PR-29A probe. Be careful as these volatges are lethal and on the order of 950 Volts in receive and 780 volts in trransmit. Never sample the plate supply voltage at the tube caps since there will be RF as well as DC there. SAmple the voltages at the PS caps or at the plate choke coil.

I have a close to mint VFO820 that works perfectly that I would like to sell. It is complete with cable, original instructions and warranty card. $125 shipped and I can take Paypal.

I am also considering selling my TS-820. It has the 500Hz CW filter, original service manual and original noise cancelling Kenwood hand mic. I would sell the package (TS-820s/VFO-820) for $350 but would as soon not ship. If you are local in So. Cal. I could arrange to meet for delivery.

Please email me at af6ni@... if interested.

Thanks and 73.

Topic: 31357 Message: 31357

I am trying to determine if I am experiencing "low receive" on my TS-520 or if I need to adjust the s-meter. This rig sat idle for close to 20 years. A few months ago I went through the rig and cleaned all the pots, relays, and variable caps. I also did some tuning on the coil pack following the procedure in the book. All in all the rig seems ok and the receive, especially 10m, seemed to respond to tuning the coil pack because it does have more sensitivity (according to s-meter and ear) than before the tuning. I can seem to "hear" pretty good with the rig and have worked a few DX stations with it over the last few weeks. However, I have noticed that it seems pretty "tight" as far as the s-meter is concerned. When I do the 25khz marker test I get varing results depending on the band. With 10m I can only get about 3 s-units with the marker... on 20m (I think its 20m) about the best I can get is about 6-1/2 to 7 s-units. This afternoon I was listening on 20m and heard a station that is local to me... only about 2 miles down the road. I am not familiar with the station I was listening to so I do not know what antenna he was using or its orientation. I have a dipole up about 25 feet. Seems I can remember, back when the rig was newer, stations that would easily do 20+ s-units but that does not seem to be the case now. Is there an easy straight forward way to determine if it is the receive or s-meter that is "tight" with out a lot of sophisticated equipment (that I don't have)? I know that meter don't mean much but it is a way to judge things "relativly."

Thanks,

Dan KI4AX

Dan,

I would pay close attention to the IP idling current in transmit. If it starts to show instability, stop transmitting and replace the final tubes. I also would not trust the filter capacitors either. It's quite possible the filter capacitors have aged to the point they need to be replaced. 20 years is a long time for a radio to sit without being powered on. I recommend replacing the power supply filter capacitors before you continue operating the 520.

As for low S meter reading, the S meter sensitivity and Zero pots could be dirty/corroded which could be causing the S meter to be less than normal. Have you checked the service manual's first step, measured and adjusted, if necessary, the 9VDC and 3.3VDC? If not then check these voltages. Perform the voltage adjustment steps in the order given in the service manual.

The driver and both final tubes will have nothing to do with the low S meter reading. You should see at least S9 or higher S meter reading on 80 meters with the calibrator turned on and the VFO adjusted for a beat note at 25Khz intervals on the dial. The S meter will be less as you go higher in bands.

The band switch settings are

1.8 = 160 meters
3.5 = 80 meters
7 = 40 meters
14 = 20 meters
21 = 15 meters
28/28.5/29/29.5 = 10 meters

If you have the first 520 model, not 520S or 520SE, then you won't have 160 meters, only 80 thru 10. 160 meters wasn't included until the 520S and 520SE.

73s
Mike
W5RKL

A few months ago I went through the rig and cleaned all the pots, relays, and variable caps. I also did some tuning on the coil pack following the procedure in the book. All in all the rig seems ok and the receive, especially 10m, seemed to respond to tuning the coil pack because it does have more sensitivity (according to s-meter and ear) than before the tuning. I can seem to "hear" pretty good with the rig and have worked a few DX stations with it over the last few weeks. However, I have noticed that it seems pretty "tight" as far as the s-meter is concerned. When I do the 25khz marker test I get varing results depending on the band. With

10m I can only get about 3 s-units with the marker... on 20m (I think its 20m) about the best I can get is about 6-1/2 to 7 s-units. This afternoon I was listening on 20m and heard a station that is local to me... only about 2 miles down the road. I am not familiar with the station I was listening to so I do not know what antenna he was using or its orientation. I have a dipole up about 25 feet. Seems I can remember, back when the rig was newer, stations that would easily do 20+ s-units but that does not seem to be the case now. Is there an easy straight forward way to determine if it is the receive or s-meter that is "tight" with out a lot of sophisticated equipment (that I don't have)? I know that meter don't mean much but it is a way to judge things "relativly."

Mike,

Thanks for your response to my post about low receive. I will keep an eye on the idle Ip for stability. So far I haven't noticed any problem with it but I have not exactly been looking at it either. When I went through the rig and cleaned all the pots I also replaced the HV caps using the HV kit from Ken K4EAA, checked and adjusted the 9v and the 3.3v regulated voltages, and cleaned the vox and transmit/ antenna relay. There was one set of contacts in the tx/ant relay that seemed pretty dirty but also seemed to clean up pretty good. Tx does not seem to have any problems.... I have several very excellent reports including the outstanding audio like a kenwood with a shure 444 mic should. Its the receive I'm not sure about. As I started to say, in my previous post, a station 2 miles from mine, barefoot, only develops about an 8.5 to 9 s-units. But I seem to hear ok.

I will see if I can clean the s-meter pots and see what happens. I will also check the marker strenth on 80m as you have suggested.

Thanks for your help Mike,

Dan KI4AX

I also would not trust the filter capacitors either. It's quite possible the filter capacitors have aged to the point they need to be replaced. 20 years is a long time for a radio to sit without being powered on. I recommend replacing the power supply filter capacitors before you continue operating the 520.
>
> As for low S meter reading, the S meter sensitivity and Zero pots could be dirty/corroded which could be causing the S meter to be less than normal. Have you checked the service manual's first step, measured and adjusted, if necessary, the 9VDC and 3.3VDC? If not then check these voltages. Perform the voltage adjustment steps in the order given in the service manual.
>
> The driver and both final tubes will have nothing to do with the low S meter reading. You should see at least S9 or higher S meter reading on 80 meters with the calibrator turned on and the VFO adjusted for a beat note at 25Khz intervals on the dial. The S meter will be less as you go higher in bands.

I've not pulled my service manual so I do not know which procedures are referenced that require an 8 ohm dummy load. Generally any non-inductive resistor of the same resistance can be substituted for a dummy load. The power requirement will need to be met. For example if the dummy load is 8 ohms at 5 watts then an 8 ohm non inductive resistor can be used.

The difference in a VTVM and AF VTVM will be the frequency response and a VTVM may not have a dB scale. Generally an AF-VTVM will have logarithmic voltage scales and a dB scale although some may have linear voltage scales. An AF VTVM would be used for DC and AF since any small amount RF will not affect (or minimally affect) the reading(s).

Greetings group,

   In the furtherance of my knowledge base...I need to ask a couple of questions regarding procedures in the service manuals(several models):

        What can be used/ substituted for the 8 ohm "dummy load" used for several procedures.

         Can a regular VTVM be used in place of an AF VTVM?

          I am trying to become self sufficient as much as possible

          tnx   73's   joe   wb7uqu

Dan:

I have the same situation with my TS-520. Even when the received station is loud and clear the S-meter barely registers. And using the calibrator the S-meter indication seems to be too low on any band.

But - I have worked Poland, Germany, and Italy on 15 meters USB over the past week using a dipole strung in my attic, so I am not worried about what the S-meter says. I'll open it up and see if I can adjust the S-meter sometime. In the meantime I give the other station an S-meter reading but tell them not to believe it.

The reason I mentioned monitoring the IP current was because I experienced a similar issue with a Heathkit HW-101 that sat for 22 years, never powered up. After cleaning, inspecting, and replacing obvious bad parts and loose connections, I was able to power the transceiver up. It worked fine for about 4 days, 105 watts output, good receive, and no instability UNTIL the first Saturday morning. I place the transceiver in TUNE and notice the PLATE current meter, same as IP in the Kenwood hybrids, was fluctuation up and down (instability). This happened about 4 times then all of a sudden the PLATE current soared full scale and tripped the HP-23 power supply breaker. At the same time the current soared, the final tubes arced. I reset the breaker, turned the transceiver back on and it worked fine, as long as I didn't transmit. The moment, fraction of a section is how long it took, I switched to transmit, PTT, CW key, etc, the IP current soared full scale, final tubes arced, and the power supply breaker tripped.

I tested the tubes and both tubes tested "good". I replaced both final tubes with known good tubes, problem solved.

Air/gasses can enter the tube's vacuum over time through openings around the base pin. As the tubes are heated, cooled, heated, cooled, many times, the seals around the tube pins becomes less, allowing gas accumulation inside the tube. When current flow within the tube occurs and I'm not talking about filament voltage but rather electron flow from the cathode to the screen and ultimately the plate, arcing can occur. When this happens, throw the tubes away and installed known good tubes.

You can't eliminate the gas accumulation in the tubes by letting the tubes sit with no conduction and filament voltage only. Tubes like the 6146 have Barium as the gas absorbing material. If you look closely on the side of the tube's plate area there may be a round element and the inside of the tubes around the area of this element is shinny "silver" or 'chrome'. The shinny silver/chrome coating is the result of the "getter flash" that occurs during the last stage of the tube's construction. The getter flash absorbs any residual gas that may remain after the vacuum producing stage of construction. Most low power and receiving tubes have this silver/chrome inner coating and behind or at the coating area on the inside of the tube is where you will see the getter element. The element may be a round "ring", "square" shaped element which is the getter element. When the tube conducts, heat is produced. Heating the getter element helps to eliminate gas in the tube. Filament only power will not produce sufficient heat to allow the getter element to absorb gas, the tube has to conduct (be in operation) for the getter element to work. If the shinny/chrome coating turns "white", that's an indication there is a crack in the glass envelope and there is no more vacuum inside the glass envelope. When you see this, throw the tube away, you can't fix it.

High power tubes such as the 3-500Z, 4-400, 813, 572B, and 811A, for example, have their plates coated with Zirconium. The plates appear to be a dusty gray color. The gray dusty coating is Zirconium. Zirconium is used to absorb gases inside the tube. Zirconium is not used in small receiving/low power tubes such as the 6146, 12AX7, 6EA8, etc.

For Zirconium to absorb gases, the plate must be heated to a very high temperature, approximately 1,000 degrees centigrade. A sign the plates are heated to this high temperature is the plates will show a dull red glow during transmissions. This is "normal" and should not be thought of as a problem. The worse thing one can do, when operating 4-400, 3-500Z, 811A, etc, is to operate the tube during transmissions with the plate NOT showing a dull red glow.

Small receiving and low power transmit tubes such as the 6146, sweep tubes, 12AX7, 12BY7, the plates of these tubes should never show any color! If they do then the tube itself is bad or the circuit is causing excessive current to flow, or there's a short in the tube elements or the circuit. I've seen 12AX7 plates glow a dull red. I couldn't see the red glow until I turned the lights out and visually inspected the tube's in a dark room. The tube turned out to be bad.

Robert,

I'm thinking that it may just be the meter, also, but I would like to make a determination one way or the other if I can. I know I should not let things like this bother me but I guess its just my nature. I just don't want to go in and turn the meter up if it doesn't deserve to be turned up... if you know what I mean. If I can't figure it out with out a lot of test gear I guess it will wait until I can find someone with the gear I need. Like you, I have been making some nice DX contacts with it so I guess its not doing too poorly.

Thanks,

Dan KI4AX

The S meter is controlled in the 520 by Q7 and Q8, meter amplifier. The last IF signal is applied to the AGC circuit where AGC voltage is produced. The AGC voltage is applied to the IF and RF amplifiers to control the gain of these 2 stages. In addition, the AGC voltage is also applied to the meter amplifiers and depending on the meter zero and sensitivity pots are set determines how well the AGC voltage is displayed as 'S Units' on the meter in receive.

Follow the 520's service manual's S meter adjustments to correct this problem. Naturally, the rest of the receive sections must also be working properly for this adjustment to be correct.

If the meter is displaying correct ALC, HV, RF, and IP indications then the meter's not the problem.

I know I should not let things like this bother me but I guess its just my nature. I just don't want to go in and turn the meter up if it doesn't deserve to be turned up... if you know what I mean. If I can't figure it out with out a lot of test gear I guess it will wait until I can find someone with the gear I need. Like you, I have been making some nice DX contacts with it so I guess its not doing too poorly.

to adjust the s-meter. This rig sat idle for close to 20 years. A few months ago I went through the rig and cleaned all the pots, relays, and variable caps. I also did some tuning on the coil pack following the procedure in the book. All in all the rig seems ok and the receive, especially 10m, seemed to respond to tuning the coil pack because it does have more sensitivity (according to s-meter and ear) than before the tuning. I can seem to "hear" pretty good with the rig and have worked a few DX stations with it over the last few weeks. However, I have noticed that it seems pretty "tight" as far as the s-meter is concerned. When I do the 25khz marker test I get varing results depending on the band. With 10m I can only get about 3 s-units with the marker... on 20m (I think its 20m) about the best I can get is about 6-1/2 to 7 s-units. This afternoon I was listening on 20m and heard a station that is local to me... only about 2 miles down the road. I am not familiar with the station I was listening to so I do not know what antenna he was using or its orientation. I have a dipole up about 25 feet. Seems I can remember, back when the rig was newer, stations that would easily do 20+ s-units but that does not seem to be the case now. Is there an easy straight forward way to determine if it is the receive or s-meter that is "tight" with out a lot of sophisticated equipment (that I don't have)? I know that meter don't mean much but it is a way to judge things "relativly."

31366. Continuing adventures with twins

Hi Everybody,

I've done some more work with my T-599. I have been unable to get the desired QRP response from ALC with 9 volt battery trick. One of the transistors on the control board seems to be suffering from something like secondary breakdown. I don't have a suitable replacement so I'll be shopping for the part I need. To make the postage worthwhile I'm looking at a few of the other parts in the Twins that might be vulnerable to 'accidents'. I found the remains of a burned out, melted down, crispy fried wire way down deep from some kind of past repair. That lil clue was laying right along the track of the wire from the ALC terminal, although that may not be the source of the wire fragment, nor the present ALC problem.

Even though the ALC is not working 100 per cent the transmitter is still usable. I just have to avoid overdriving it. I have no external amp to worry about. And I'll be far from overdriving it at QRP levels. Without the ALC trick I can run the output down to around two watts with only the carrier control. I actually have to turn it *up* to achieve "full" QRP power levels now. I did some deep cleaning and aligned everything but the 8 MHz bandpass filter. It behaves very well now.

Next, converters for the Twins to get on the WARC bands (30, 17, and 12 meters). The receiver already covers 30 meters in the "WWV" band. The receiver has that "EXT" (intended for 11 meters) band and that would be a good place for the 12 meter band (possibly taking advantage of the existing 10 meter hardware). That leaves the empty six meter converter bay for a place to add 17 meters. The separate converter for transmit will be driven from the "transverter" output on the T-599. More about all of those things as I get some of them done.

73,

Bill KU8H

Hi Mike and all..

Tonight I have done some voltage measurements on the tubes, as follows:- -

Pins 1, 4 and 6 are :

0V in RX and 0.417V in TX

Pin 3 RX is 242V and in TX it drops to 228V

Pin 5 RX is -94.8V and in TX it is -42.2V

These are exactly the same for both tubes.

Any comments very welcomed:

Thanks
Chris, ZL1CDP

Chris---0.417 volts across your 5 ohm cathode resistor is about 1/3 of what you should see at full load. 0.417v divided by 5 ohms equals approx 80ma plate current. Is that what your IP reading is on the rig panel meter? 80ma x 820v = 68 watts x 65% efficiency = 45 watts key down output power. I think you said you were getting about 50 watts out. Your screen voltage is OK so if your plate voltage is good then output power you are seeing is correct for how you have the rig loaded. If your panel meter Is Not reading 80 ma then your meter multipliers are not right. I think you said you replaced one of them? I am sure someone else will do the calcs and verify my assessment. I dont think there is anything wrong with your tubes or power supplies. I would take a look at your meter multipliers again. Keep at it you will solve this one. 73s Terry K9TW

Hi Chris,

What position was the MODE switch set to when you measured the voltages in transmit? It appears you have the Mode switch set to either LSB or USB.

If the final tube cathode resistors are within tolerance and the final amplifier is tuned up properly for full output (220ma showing on the IP meter), the cathode voltage on the final tubes (pins 1, 4, or 6) will be approximately 1.125VDC.

The transmit cathode voltage (pins 1, 4, and 6) indicates 60ma of idling current flowing in the final tubes, no RF output.

The final tubes are wired in parallel. That's why the voltages are the same on both tubes.

73s
Mike
W5RKL

Chris---The external meter is a watt meter-- correct? The 160 ma is the IP reading on your rig meter-- correct? With .417 volts across a 5 ohm cathode resistor you cannot have 160ma plate current. Unless your 5 ohm cathode resistors are not actually 5 ohms. I would go back and read the parallel combination of your 4 -20 ohm resistors. Maybe you read the color code wrong when you replaced them. It is easy to do. Also, my schematic shows R10 to be 4.7k ohm and that is what is installed in my rig. R6 is 2.7k so my multipliers are approx 2/3 ratio. I dont know what the panel meter FS is or the internal resistance. I suppose it is possible that Kenwood used different meters for different production runs but that would be unusual. The pros on here would know if they used different meters that required different meter multipliers. If your 160 ma IP reading is correct then .417/.160 = 2.60 ohm cathode resistor.
Terry

Topic: 31320 Message: 31372

I agree with Terry.

If the cathode resistors are 5 ohms and the 830 tunes up with 220ma showing on the IP meter, then the cathode voltage will be approximately 1.125VDC. You can determine how the final amplifier is working by monitoring the cathode voltage (pins 1 on the final tube sockets).

If the cathode resistors increase in value by only "1" ohm resulting in a cathode resistance of 6 ohms and the same 220ma is indicated on the IP meter, the cathode voltage will be approximately 1.35VDC instead of approximately 1.125VDC.

Example:
Cathode resistance is 5 ohms
Final amplifier current at max power output is 220ma
Cathode voltage is 1.125VDC

E = I x R

or

.220 x 5 = 1.125VDC

Cathode resistance has changed to "6" ohms
Same final amplifier current, 220ma
Cathode voltage is now "1.35VDC".

Notice the increase in cathode voltage by an increase of only "1" ohm of cathode resistance.

If the final amplifier is showing 160ma and the cathode resistors are within tolerance, 5 ohms, then the cathode voltage will be approximately .8VDC (.160 x 5 = .8VDC).

If the IP meter indicates 60ma with no RF output, the cathode resistors are within tolerance, 5 ohms, the cathode voltage will be approximately .3VDC (.060 x 5 = .3VDC).

The cathode voltage will tell you a lot of how the final amplifier is working.

From: Terry Wagoner
Topic: 31320 Message: 31373

Hi Mike--I hate to sit on the side line! Maybe Chris should retrace his steps?
Problem/Symptoms:
1. 75 watts output with 200ma IP........ normal/ok
2. Suddenly 50 watts output with 200ma IP.........Driver tube? Plate/Screen Voltage low? Cathode Resistors increasing in value?
3. Suddenly "0" watts output, "0" ma IP, "0" alc, EP 800+.............Open cathode resistors most likely cause (didnt hear them pop)

Actions:
1. Replaced Cathode Resistors.......Back to 50 watts out for 200ma IP
2. Replaced R10 (6.8k) with a 10K resistor......Why make this mod? Suspected panel meter not reading accurately?
3. Measured all tube voltages with 50 watts out and IP reading approx 160 ma.....Cathode voltage and IP do not compute for 5 ohm resistor

Suggested Actions:
1. Make sure voltage readings taken in keydown CW mode. Should not get 50 watts out if measuring in USB or LSB with mike keyed.
2. Re-measure cathode resistors
3. Remove meter multiplier mod and install new 2.7K R6 and 4.7K R10 to restore meter circuit to factory as-built configuration
4. Re tune rig to 225ma IP and report output power to the group
5. Sell rig to Mike or Terry for $50.00!

Mike--dont you just want to fly over and get your hands on this problem! My favorite part of the hobby!

Mike,

When I said I think it is the meter, in my previous post, I meant the adjustments... I didn't mean the actual meter. The meter it self works fine and displays the correct ALC, HV, RF, and Ip. First chance I get I will address the adjustments for the meter by cleaning and adjusting.

I enjoyed reading the information on vacume tubes. I was aware of the getter elements in some tubes but did not know about the other coatings and methods of removing gas from tubes. Now that you mention it I did have to replace the driver tube, in this rig, when I first fired it up because it turned white. The replacement was NOS and tested before it went in. I also re-aligned the driver coil afterwards.

I will keep an eye out for the fluctuating Ip but so far so good.

Thanks,

Dan

I know I should not let things like this bother me but I guess its just my nature. I just don't want to go in and turn the meter up if it doesn't deserve to be turned up... if you know what I mean. If I can't figure it out with out a lot of test gear I guess it will wait until I can find someone with the gear I need. Like you, I have been making some nice DX contacts with it so I guess its not doing too poorly.

> > > >
> > > > I am trying to determine if I am experiencing "low receive" on my TS-520 or if I need to adjust the s-meter. This rig sat idle for close to 20 years. A few months ago I went through the rig and cleaned all the pots, relays, and variable caps. I also did some tuning on the coil pack following the procedure in the book. All in all the rig seems ok and the receive, especially 10m, seemed to respond to tuning the coil pack because it does have more sensitivity (according to s-meter and ear) than before the tuning. I can seem to "hear" pretty good with the rig and have worked a few DX stations with it over the last few weeks. However, I have noticed that it seems pretty "tight" as far as the s-meter is concerned. When I do the 25khz marker test I get varing results depending on the band. With 10m I can only get about 3 s-units with the marker... on 20m (I think its 20m) about the best I can get is about 6-1/2 to 7 s-units. This afternoon I was listening on 20m and heard a station that is local to me... only about 2 miles down the road. I am not familiar with the station I was listening to so I do not know what antenna he was using or its orientation. I have a dipole up about 25 feet. Seems I can remember, back when the rig was newer, stations that would easily do 20+ s-units but that does not seem to be the case now. Is there an easy straight forward way to determine if it is the receive or s-meter that is "tight" with out a lot of sophisticated equipment (that I don't have)? I know that meter don't mean much but it is a way to judge things "relativly."

Hi Terry and Chris,

I question the same 200ma IP current indication with 2 different power outputs. If the controls were not touched, the 830 was producing 75 watts output at 200ma then the power output suddenly dropped to 50 watts, the IP meter should display a "different" current indication, typically less IP current. This is assuming there has been no change in load to the transmitter (dummy load, SWR, etc) and the controls remained the same. The HV indication would also be different, HV would be slightly higher.

As current flows through the final tubes, a voltage drop occurs across the HV supply. This voltage drop results in the HV indication to be "less" as the current through the tubes increases. The opposite occurs when the current through the tube "decreases". This can be seen by monitoring the final tube's cathode voltage. As current through the tube increases so does the cathode voltage. As the current through the tubes "decreases" so does the cathode voltage.

Chris, if R10 was originally 4700 ohms 1/2 watt but you changed R10 to 10K 1/2 watt because someone said their schematic shows R10 as 10K, that is a bad idea! If you changed R10 from 4700 ohms to 10K ohms then the IP meter indications will be wrong. Change R10 back to 4700 ohms 1/2 watt.

Chris, I recommend you tune the 830 up into a dummy load for full output. The IP meter should indicate approximately 225ma and the cathode voltage should be 1.125VDC at full output. If this is what you see but your watt meter shows only 75 watts then I suspect your watt meter is at fault, not the 830.

Topic: 31320 Message: 31376

Hi Terry,

If the cathode resistors are open, the cathode current path changes from the normal 4 cathode resistors to R6 and R10 series string. This would result in the IP indication, in transmit, to peg the meter full scale ot the right. There doesn't appear to be any indication of this.

Loss of IP current can be caused by the relay on the AF Unit. When the terminals of the AF Unit relay fail, the final tube's bias voltage remains at the "receive" or "standby" level which results in a "zero" IP current indication. This also causes the HV to remain at the receive or standby level as well, approximately 950VDC or so. If both of these indications are true then loss of IP current in transmit is not caused by bad cathode resistors.

R10 in the 830 is 4700 ohms not 6800, unless I missed something.

As I said in my last response, I would tune up into a dummy load for maximum power output, monitor the cathode voltage, and if the IP indications are 225ma and the cathode voltage is 1.125VDC then the final amplifier is producing maximum input power. If this is true then I suspect the watt meter is at fault not the transceiver. Remember, the same "225ma" of IP current is also flowing through the cathode resistors. Therefore, (E = I x R) .225 x 5 = 1.125VDC of cathode voltage. This is assuming the cathode resistors are within 10% tolerance. A higher cathode voltage at full output displaying the same 225ma IP current will indicate one or more of the cathode resistors have changed values.

I believe Chris said cathode resistor R3 was open. If that's true than the cathode resistance is no longer 5 ohms but approximately 6.666 ohms. This will result in a increase in cathode voltage to approximately 1.499VDC instead of 1.125VDC when all 4 cathode resistors are within tolerance.

Date: 2011-05-18 14:41:35 UTC
From: Terry Wagoner
Topic: 31320 Message: 31377

Hi Mike--That is why I suggested Chris re-trace his steps. It is kind of running together and I may be confusing with another poster? I thought he said he tried a different wattmeter and different coax jumpers? Also, pretty sure he said he replaced a 6800 ohm with a 10k ohm. Yes -it should be a 4700 ohm according to my schematic and experience. If it was a 6800 ohm someone else had modified the meter multiplier circuit. I am a big believer in putting rig back to factory config and going from there. If he has reasonably accurate watt meter and has 50 watts out now, problem cant be too difficult to diagnose. Sure sounds like cathode resistors are not 20 ohms and he is not tuning rig as hard as he believes he is or modified meter circuit is fooling him. Will be interested to see what he finds.

By the way I worked Russia Vlad R4WB last nite around 1030 on 20 meters with pretty noisy conditions. Was able to break pile up with my barefoot TS-830S and a trapped dipole at 25 feet. Got a 5x9+ report. That is a lot of fun. These old "dip and load" rigs are great! Have great day Mike. Terry

Subject: [TS-520_820_530_830] Re: Transmit has died

Hi Terry,

If the cathode resistors are open, the cathode current path changes from the normal 4 cathode resistors to R6 and R10 series string. This would result in the IP indication, in transmit, to peg the meter full scale ot the right. There doesn't appear to be any indication of this.

Loss of IP current can be caused by the relay on the AF Unit. When the terminals of the AF Unit relay fail, the final tube's bias voltage remains at the "receive" or "standby" level which results in a "zero" IP current indication. This also causes the HV to remain at the receive or standby level as well, approximately 950VDC or so. If both of these indications are true then loss of IP current in transmit is not caused by bad cathode resistors.

R10 in the 830 is 4700 ohms not 6800, unless I missed something.

As I said in my last response, I would tune up into a dummy load for maximum power output, monitor the cathode voltage, and if the IP indications are 225ma and the cathode voltage is 1.125VDC then the final amplifier is producing maximum input power. If this is true then I suspect the watt meter is at fault not the transceiver. Remember, the same "225ma" of IP current is also flowing through the cathode resistors. Therefore, (E = I x R) .225 x 5 = 1.125VDC of cathode voltage. This is assuming the cathode resistors are within 10% tolerance. A higher cathode voltage at full output displaying the same 225ma IP

current will indicate one or more of the cathode resistors have changed values.

I believe Chris said cathode resistor R3 was open. If that's true than the cathode resistance is no longer 5 ohms but approximately 6.666 ohms. This will result in a increase in cathode voltage to approximately 1.499VDC instead of 1.125VDC when all 4 cathode resistors are within tolerance.

Greetings group,

TNX to those who put in their 2 cents. The wording about being "self sufficient" was poor. What I meant by that was....I don't want to beg or borrow equipment. I pretty much have "the basics," just need to really learn how to use them. My home town lost it's only electronic store after 40+ years. Anything above the crap that "Radio Shack" sells either has to be mail ordered or I have to drive to Seattle. I want to make sure that when I adjust/service or, otherwise mess with a rig I am keeping it operating within the regulations and good radio practices. Thanks again.....

Subject: Re: [TS-520_820_530_830] service equip. question

I've not pulled my service manual so I do not know which procedures are referenced that require an 8 ohm dummy load. Generally any non-inductive resistor of the same resistance can be substituted for a dummy load. The power requirement will need to be met. For example if the dummy load is 8 ohms at 5 watts then an 8 ohm non inductive resistor can be used.

The difference in a VTVM and AF VTVM will be the frequency response and a VTVM may not have a dB scale. Generally an AF-VTVM will have logarithmic voltage scales and a dB scale although some may have linear voltage scales. An AF VTVM would be used for DC and AF since any small amount RF will not affect (or minimally affect) the reading(s).

73,

Bill

Greetings group,

In the furtherance of my knowledge base...I need to ask a couple of questions regarding procedures in the service manuals(several models):

What can be used/ substituted for the 8 ohm "dummy load" used for several procedures.

Can a regular VTVM be used in place of an AF VTVM?

I am trying to become self sufficient as much as possible

tnx 73's joe wb7uqu

Bill,

The 8 ohm dummy load is used as an 8 ohm load to the speaker output when monitoring the audio signal with a VTVM.

I never have less than 100 W output when tuned up for 200 mA of plate current on the lower bands. Ten meters is always a bit less.
If you can only get 55-60 W, I would suspect .weak tubes or componant failure somewhhere in the PA section.
I turn the carrier control up until the ALC stops the plate current from increasing and then dip the plate again. Gradually increase the loading until you get the 200-220 Ma of plate current and redip the plate (will be just a slight retuning)...
Good luck.

Subject: Re: [TS-520_820_530_830] Value of R10 in the Final Unit - TS-830s

,

My experience with these hybrids using a good 12BY7A driver and good 6146 finals is that with the CW (constant carrier) output into a dummy load is 55-60 Watts at an Ip reading of 200 mA (using the CARRIER control) and with the plate dipped properly. Pushing the plate current any higher may result in blowing the 6 amp fuse.

Good call Mike, I will double check later today.

I am pretty certain I was in either Tune or CW though when I measured the voltages, but I may be wrong.

Cheers
Chris

Hi Terry, -

> The external meter is a watt meter-- correct?
>

Yes the external meter is a Wattmeter.

> The 160 ma is the IP reading on your rig meter-- correct?
>
Correct.

> .417 volts across a 5 ohm cathode resistor you cannot have 160ma plate current. Unless your 5 ohm cathode
> resistors are not actually 5 ohms.
>
Well that;s what the meter on the 830 is telling me Terry... I will check again, but I only just replaced the cathode resistors as one was open, so I replaced all four to be on the safe side.
Once replaced, I checked and they was reading around 5.4 Ohms when in-line, so that should be good.

> I would go back and read the parallel combination of your 4 -20 ohm resistors.
>

I will do this later.

> Maybe you read the color code wrong
> when you replaced them. It is easy to do.
>

No, they were in a pack from Jaycar Electronics - pack of 8 x 1/2 watt 20Ohm resistors... I also measured them before putting them into the final unit. 20 Ohms (give or take) each.

> Also, my schematic shows R10 to be
> 4.7k ohm and that is what is installed in my rig. R6 is 2.7k so my multipliers are approx 2/3 ratio.
>

This (I think), is where the problem may lie. - As i stated in my original post about this, I have two different final unit schematics...one shows R10 as a 4.7K resistor, the other shows R10 as a 10K resistor... which is why I asked what the value of R10 should be.... - The R10 resistor that I removed read around 6.7K - I assumed that it was supposed to be 4.7K and reading high, and was about to swap it for another 4.7K that I have, but then saw the second schematic showing R10 as a 10K resistor... confused, so I asked the question on here.

What I may do, is replace the 10K resistor that is now in the R10 position with a 4.7K resistor and see what the meter reads. - Naturally, this will not alter the power out

problem I have.

Just for reference, I follow the K4EAA tune up procedure to the letter, but since my TX died, I have no more than around 55W out and the IP reads low (around 160mA maximum for the maximum power out that I can obtain.... - 55W)

Cheers
Chris

Hahaha... Terry, that's genius (both the comedy at the end of the email and the logic).

Joe,

An 8 ohm 2 watt resistor connected across the receiver's speaker terminals can serve as an 8 ohm "dummy load" for the receiver's audio output.

Any VTVM that can measure "AC" voltage can be used where an "AF VTVM" is called for.

Audio has an "AC Sine Wave" component where the signal, if viewed on an oscilloscope, will look like a circle cut in half with the bottom half swung to the right. That's "1 cycle" or "1 hertz" (abbreviated "HZ"). There are "1,000" hertz in "1 Kilohertz". "Kilo" is "1,000".

RF has the same AC sine wave component.

AC and RF voltages can pass through a capacitor but DC voltage cannot.

You can perform a simple and safe experiment with a receive, signal generator, and a simple disc capacitor, say .01ufd at 50VDC.

First, connect the capacitor in "series" with "positive" speaker wire and the other speaker wire to the receiver's chassis.

Next, turn the calibrator "ON" and tune the VFO for a beat note. Notice you hear the beat note in the speaker even though there is no "direct" connection to the receiver's "positive" speaker connection and the positive speaker wire.

Next, connect the same capacitor in series with the "positive" lead of your signal generator and the receiver's positive antenna terminal. Connect the signal generator's ground to the receiver's ground.

Now, tune the generator to the receiver's frequency and notice the S meter rises. If the signal generator has a built in tone generator, most do, turn the tone generator ON. Notice you hear the signal generator's tone generator in the receiver's speaker.

These 2 simple and safe experiments show you that an AF and RF signal voltages will pass through a capacitor while a DC voltage will not.

You do another simple and safe experiment with a AA battery, the same capacitor, and a speaker. Connect one lead of the capacitor to the batteries positive terminal. Connect the other lead of the capacitor to one of the speaker terminals. Connect the other speaker terminal to the battery's negative terminal. You didn't hear a thing did you? That's because DC cannot flow through a capacitor like AF and RF voltage can. If DC could flow through a capacitor, the instant you connected the negative battery terminal to the speaker terminal you would hear a "pop" but you didn't and, again, that's because DC voltage cannot flow through a capacitor.

73s
Mike

OK Chris not questioning your competence just trying to cover all bases. It is easy to make a mistake. I of course never have! Yes 5.4 ohms is good and well within tolerance for your new cathode resistors. So if your .417 volts across the 5.4 ohm cathode resistors is correct then you only have approx 80 ma of plate current and not 160 ma. That is Ohms law and would account for your low output power. Unless of course the .417 wasnt read keydown in CW mode. I will back out now as you are getting lots of help and Mike and others are more experienced than I am. I will read with interest as I want to learn from this.
73s Terry

Hi Terry, -

> The external meter is a watt meter-- correct?
>

Yes the external meter is a Wattmeter.

> The 160 ma is the IP reading on your rig meter-- correct?
>
Correct.

> .417 volts across a 5 ohm cathode resistor you cannot have 160ma plate
>current. Unless your 5 ohm cathode
>
> resistors are not actually 5 ohms.
>
Well that;s what the meter on the 830 is telling me Terry... I will check again, but I only just replaced the cathode resistors as one was open, so I replaced all four to be on the safe side.
Once replaced, I checked and they was reading around 5.4 Ohms when in-line, so that should be good.

> I would go back and read the parallel combination of your 4 -20 ohm resistors.
>

I will do this later.

> Maybe you read the color code wrong
> when you replaced them. It is easy to do.
>

No, they were in a pack from Jaycar Electronics - pack of 8 x 1/2 watt 20Ohm resistors... I also measured them before putting them into the final unit. 20 Ohms (give or take) each.

> Also, my schematic shows R10 to be
> 4.7k ohm and that is what is installed in my rig. R6 is 2.7k so my multipliers
>are approx 2/3 ratio.
>

This (I think), is where the problem may lie. - As i stated in my original post about this, I have two different final unit schematics...one shows R10 as a 4.7K resistor, the other shows R10 as a 10K resistor... which is why I asked what the value of R10 should be.... - The R10 resistor that I removed read around 6.7K - I assumed that it was supposed to be 4.7K and reading high, and was about to swap it for another 4.7K that I have, but then saw the second schematic showing R10 as a 10K resistor... confused, so I asked the question on here.

What I may do, is replace the 10K resistor that is now in the R10 position with a 4.7K resistor and see what the meter reads. - Naturally, this will not alter the power out problem I have.

Just for reference, I follow the K4EAA tune up procedure to the letter, but since my TX died, I have no more than around 55W out and the IP reads low (around 160mA maximum for the maximum power out that I can obtain.... - 55W)

Cheers
Chris

Hi Terry, not reading your comments as a question of my competence at all.!! ;-)

I'm relatively new to the Hybrid scene, so need all of the guidance I can get!! - you are doing a great job of helping, so please don't stop now!.

Cheers
Chris

Topic: 31320 Message: 31387

Chris and others,

The "10K" resistor for R10 is for the TS-830M. R10 in the TS-830S is 4.7K. Replace the 10K with a 4.7K if your TS-830 is NOT the "M" model. The "M" model has "AM" mode which the TS-830S does not have.

Lets assume the final amplifier is producing a cathode voltage of 1.125VDC at full output.

Lets also assume that R10 is 4.7K and R6 is 2.7K, both resistors are within tolerance.

Using ohms law, you can determine the voltage at the junction of R6 and R10 which is fed to the meter when the meter switch is set to IP in transmit mode. The following examples assume the 830 is producing a stable full carrier output in CW mode, not sideband. Sideband will cause the cathode voltage to "vary" because of the variable frequencies in the audio applied to the balance modulator which causes the RF power to vary based on the speech amplifier's output.

So, we first have to determine the current through R6 and R10. We do this because we have 2 of the required values, Resistance and voltage, but we don't have the 3rd, the current. To get the current we use ohms law, I = E / R.

Therefore, with 1.125VDC applied to the series string of R6 and R10, the current through the string will be:

1.125 / 7400 = .000152027

Now to determine the voltage drop across R6 we use ohms law again,

E = I x R

.000152027 x 2700 = .410472VDC

The remaining .714527VDC will be dropped across R10.

.000152027 x 4700 = .714527VDC

I rounded off the last digit "6" to "7" since the next digit after "6" is "9".

Are we sure this is correct? We can determine this by adding both voltage drops, .410472 and .714527 together. If they equal the source voltage of "1.125VDC" then we have done our math right and .410472VDC is the correct voltage drop across R6.

.410472 + .714527 = 1.12499997VDC

Close enough for Government work so our math is right.

Now, lets see what happens when we change R10 to "10K" but leave R6 at 2.7K.

First, we need the total resistance which is 12.7K,

2700 + 10000 = 12700

Next, we need to determine the current through R6 and R10 which is

I = E / R

or

1.125 / 12700 = .0000885826

Next, we determine the voltage drop across R6, which is 2.7K.

E = I x R

.0000885826 x 2700 = .239173

Again, the remaining voltage is dropped across R10 which is now 10K

.0000885826 x 10000 = .885826VDC

Check out math;

.239173 + .885826 = 1.124999VDC

So we are correct in our calculations. But, there is a difference.

Notice the different voltage drop across R6 with R10 being 10K. That's a difference of

.410472 - .239173 = .171254VDC

That may not seem like a lot but it can result in an erroneous IP meter indication.

If you swapped R6 and R10 around, meaning R6 would be 4700 and R10 would be 2700, the meter would be looking at a different voltage drop across R6. Try it to see what you get.

Therefore, change R10 back to 4.7K 1/2 watt and ensure R6 is 2.7K 1/2 watt, both within tolerance of 10%. This will make the IP meter display the correct cathode current.

73s
Mike
W5RKL

Mike--I did back of envelope calcs which revealed meter requires 1.0 volt drop across R10 for full scale deflection. That equates to approx .0286 vdc per meter division across R10. The more useful measure would be the drop across the cathode resistors. With 350 ma being indicated full scale reading that equates to approx 1.75 vdc or 0.05 vdc per each of the 35 graduated marks on the meter. So if you want to know how much drop you should see across your 5 ohm cathode resistors just multiply the indicated number of graduations x .05v. For example: 225 ma = 22.5 marks and 22.5 x 0.05 = 1.125 vdc across the cathode resistors. I cant work with all the decimal points that you can! Thanks for explaining that the different schematic and meter multipliers is for the 830M. Havent used ohms law this much since I told my professor I would rather take a sharp stick in the eye than learn Ohms Law! Sure glad he convinced me otherwise. 73s Terry

Subject: [TS-520_820_530_830] Re: Transmit has died

Chris and others,

The "10K" resistor for R10 is for the TS-830M. R10 in the TS-830S is 4.7K. Replace the 10K with a 4.7K if your TS-830 is NOT the "M" model. The "M" model has "AM" mode which the TS-830S does not have.

Lets assume the final amplifier is producing a cathode voltage of 1.125VDC at full output.

Lets also assume that R10 is 4.7K and R6 is 2.7K, both resistors are within tolerance.

Using ohms law, you can determine the voltage at the junction of R6 and R10 which is fed to the meter when the meter switch is set to IP in transmit mode. The following examples assume the 830 is producing a stable full carrier output in CW mode, not sideband. Sideband will cause the cathode voltage to "vary" because of the variable frequencies in the audio applied to the balance modulator which causes the RF power to vary based on the speech amplifier's output.

So, we first have to determine the current through R6 and R10. We do this because we have 2 of the required values, Resistance and voltage, but we don't have the 3rd, the current. To get the current we use ohms law, I = E / R.

Therefore, with 1.125VDC applied to the series string of R6 and R10, the current through the string will be:

1.125 / 7400 = .000152027

Now to determine the voltage drop across R6 we use ohms law again,

E = I x R

.000152027 x 2700 = .410472VDC

The remaining .714527VDC will be dropped across R10.

.000152027 x 4700 = .714527VDC

I rounded off the last digit "6" to "7" since the next digit after "6" is "9".

Are we sure this is correct? We can determine this by adding both voltage drops, .410472 and .714527 together. If they equal the source voltage of "1.125VDC" then we have done our math right and .410472VDC is the correct voltage drop across R6.

.410472 + .714527 = 1.12499997VDC

Close enough for Government work so our math is right.

Now, lets see what happens when we change R10 to "10K" but leave R6 at 2.7K.

First, we need the total resistance which is 12.7K,

2700 + 10000 = 12700

Next, we need to determine the current through R6 and R10 which is

I = E / R

or

1.125 / 12700 = .0000885826

Next, we determine the voltage drop across R6, which is 2.7K.

E = I x R

.0000885826 x 2700 = .239173

Again, the remaining voltage is dropped across R10 which is now 10K

.0000885826 x 10000 = .885826VDC

Check out math;

.239173 + .885826 = 1.124999VDC

So we are correct in our calculations. But, there is a difference.

Notice the different voltage drop across R6 with R10 being 10K. That's a difference of

.410472 - .239173 = .171254VDC

That may not seem like a lot but it can result in an erroneous IP meter indication.

If you swapped R6 and R10 around, meaning R6 would be 4700 and R10 would be 2700, the meter would be looking at a different voltage drop across R6. Try it to see what you get.

Therefore, change R10 back to 4.7K 1/2 watt and ensure R6 is 2.7K 1/2 watt, both within tolerance of 10%. This will make the IP meter display the correct cathode current.

73s
Mike

I have the same experience with mine and looked carefully at the band indicators on the plate dial. I have concluded the indicators refer to range bands around the dial, rather than precious points. The 80 meter range for example usually tunes so that the point on the range is closer to the straight up (12 O'clock) position than the tune point for the 40 meter band (which is not the same range indicator.) I hope this makes some sense to you. It took me a while to figure it out on my TS 540 SP.

Rick, yes it sort of makes sense, but it would seem like it should show
an indication of around 7mhz when tuning in the 7 mhz band...

an indication of around 7mhz when tuning in the 7 mhz band...
Bill

None of mine were ever real close. Tune for the peak with the grid drive and the dip with the plate tuning, and don't worry about what the dial says. If it makes you feel better you can slip the pointer around to the proper position, but it doesn't change anything.

The plate Tune is only a guide and wasn't intended to point to a specific frequencies.

Much depends on the condition of the finals and the impedance of the load you are tuning into.

Also, there may be some interaction between the Load control and the plate pointer.

Dip the plate when tuning up on a dummy load at a specific frequencie at around 100 mA Ip. And then retune at low power (Carrier control 10 to 25%) to your antenna. Use short key-downs when tuning. Always monitor Ip when tuning to save your finals.

The 820 is great rig. --- On Wed, 5/18/11, Rick Hicks <rick@...> wrote:

(or precise points if you prefer.you choose.)

I have the same experience with mine and looked carefully at the band indicators on the plate dial. I have concluded the indicators refer to range bands around the dial, rather than precious points. The 80 meter range for example usually tunes so that the point on the range is closer to the straight up (12 O'clock) position than the tune point for the 40 meter band (which is not the same range indicator.) I hope this makes some sense to you. It took me a while to figure it out on my TS 540 SP.

Hello to all,
Just received my 820 today and overall I like the radio...sounds good looks good and man its heavy...I have been using a pair of drake twins R4,T4x...which are really nice. just wanted to get a kenwood to use everyday....
my only problem so far is with the plate tuning...mine doesn't seem to line up with the band I am on..ie..when I dip the plate on 7mhz the plate tuning

indicated 3.5mhz...when I dip 14mhz its showing the 7mhz section...is
this just an adjustment??? (I am tuning into a dummy load)

From: Chris Parnell
Topic: 31320 Message: 31396

Hi Terry & Mike... thanks for all of the info

Well, I am not sure what is happening with my 830s. - I went home at lunch today and changed the 10K resistor for a 4.7K as recommended.
I tested the cathode resistance and it is 5.3Ohms

I really am wondering if there is an alignment or tube / driver issue.. I am getting VERY ODD intermittent results... i.e

Tune up procedure:
? USB, IP - Key rig and Meter shows IP of 60mA , which we know is good.

? Flick to Tune position
? Set the load control to minimum - adjust plate control for band

? Set to ALC, turn carrier to around 1/2 to 3/4 control
? Flick SEND switch and peak drive control

Symptom:
OK - here is where I start to see problems - Sometimes I get the meter pegging (even when I reduce the carrier to zero it doesn't alter).... other times the ALC goes up to around half of the meter reading (which is just above the ALC deflection scale)... one thing that I did notice is that altering the Drive control makes no difference at all to the reading.

? Switch meter to IP, Flick Send Switch and use the Plate control to dip the meter

Symptom:
Again I appear to be having intermittent issues here where IF I HAVE enough IP reading, I can dip the meter with the Plate control, but often I have such a low IP reading at this point in time it's hard to see.

etc etc...

As a very quick test I tuned for maximum Power out on my external meter (which is fine by the way, I tested it on another radio), and again it will give me around 55W (when lucky)... the IP reading around 80mA - 110mA now (which is more in line having swapped the 10K resistor for 4.7K).

When I get time later tonight, I will have to do some voltage readings (Again) :(- Any other suggestions?

Thanks
Chris Parnell

Me too! So was there a decision about the Hybrids net? Sorry, I wasn't able to follow all the discussions about it.

Bob, KD5MHQ

that is what I thought...works great though..get good dips and great
output...no worries...thanks all

Hi Chris--Your tune up procedure sounds OK to me. I have a new driver tube in as my 830 as the drive had started to slowly drift off during tune. I generally never have to have carrier control much above about 9:00 for 3/4+ meter deflection. In fact almost always have to turn carrier control down to keep it from pegging. When you are varying the drive control (you are driving the chains and varying the variable caps on the RF board) do you get a point where you see a peak on your wattmeter? I will let Mike address this as he is truly an expert. I know there are issues with the Omron relay on bottom of rig on the Audio board. Some folks carefully pop the plastic cover off and clean the contacts with paper wetted with de-oxit. Ken K4EAA sells and exact replacement. I bought one from him as a spare for future. Terry

Subject: Re: [TS-520_820_530_830] Re: Transmit has died

Hi Terry & Mike... thanks for all of the info

Well, I am not sure what is happening with my 830s. - I went home at lunch today and changed the 10K resistor for a 4.7K as recommended.
I tested the cathode resistance and it is 5.3Ohms

I really am wondering if there is an alignment or tube / driver issue.. I am getting VERY ODD intermittent results... i.e

Tune up procedure:
• USB, IP - Key rig and Meter shows IP of 60mA , which we know is good.

• Flick to Tune position
• Set the load control to minimum - adjust plate control for band

• Set to ALC, turn carrier to around 1/2 to 3/4 control
• Flick SEND switch and peak drive control

Symptom:
OK - here is where I start to see problems - Sometimes I get the meter pegging (even when I reduce the carrier to zero it doesn't alter).... other times the ALC goes up to around half of the meter reading (which is just above the ALC deflection scale)... one thing that I did notice is that altering the Drive control makes no difference at all to the reading.

• Switch meter to IP, Flick Send Switch and use the Plate control to dip the meter

Symptom:
Again I appear to be having intermittent issues here where IF I HAVE enough IP reading, I can dip the meter with the Plate control, but often I have such a low IP reading at this point in time it's hard to see.

etc etc...

As a very quick test I tuned for maximum Power out on my external meter (which is fine by the way, I tested it on another radio), and again it will give me around 55W (when lucky)... the IP reading around 80mA - 110mA now (which is more in line having swapped the 10K resistor for 4.7K).

When I get time later tonight, I will have to do some voltage readings (Again) :(- Any other suggestions?

Thanks
Chris Parnell

31400. Re: [TS-520_820_530_830] Re: Transmit has died

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-05-19 12:09:32 UTC
From: Terry Wagoner
Topic: 31320 Message: 31400

Chris--I forgot to mention some folks have some success with a "tap" test on RL1 relay. You need the rig on its side and while tuning and experiencing the intermittent ALC you can take an insulated tool and gently tap on the plastic case while watching the ALC reading. If this makes a difference you can try to clean the contacts. It is not easy to pop the cover and you can easily damage the relay. Maybe Mike or Gordon have a tool or tip for popping the cover? Terry

Subject: Re: [TS-520_820_530_830] Re: Transmit has died

Hi Chris--Your tune up procedure sounds OK to me. I have a new driver tube in as

my 830 as the drive had started to slowly drift off during tune. I generally never have to have carrier control much above about 9:00 for 3/4+ meter deflection. In fact almost always have to turn carrier control down to keep it from pegging. When you are varying the drive control (you are driving the chains and varying the variable caps on the RF board) do you get a point where you see a peak on your wattmeter? I will let Mike address this as he is truly an

expert. I know there are issues with the Omron relay on bottom of rig on the Audio board. Some folks carefully pop the plastic cover off and clean the contacts with paper wetted with de-oxit. Ken K4EAA sells and exact replacement. I bought one from him as a spare for future. Terry

Subject: Re: [TS-520_820_530_830] Re: Transmit has died

Hi Terry & Mike... thanks for all of the info

Well, I am not sure what is happening with my 830s. - I went home at lunch today

and changed the 10K resistor for a 4.7K as recommended.
I tested the cathode resistance and it is 5.3Ohms

I really am wondering if there is an alignment or tube / driver issue.. I am getting VERY ODD intermittent results... i.e

Tune up procedure:
• USB, IP - Key rig and Meter shows IP of 60mA , which we know is good.

• Flick to Tune position
• Set the load control to minimum - adjust plate control for band

• Set to ALC, turn carrier to around 1/2 to 3/4 control
• Flick SEND switch and peak drive control

Symptom:
OK - here is where I start to see problems - Sometimes I get the meter pegging (even when I reduce the carrier to zero it doesn't alter).... other times the ALC goes up to around half of the meter reading (which is just above the ALC deflection scale)... one thing that I did notice is that altering the Drive control makes no difference at all to the reading.

• Switch meter to IP, Flick Send Switch and use the Plate control to dip the meter

Symptom:
Again I appear to be having intermittent issues here where IF I HAVE enough IP reading, I can dip the meter with the Plate control, but often I have such a low

IP reading at this point in time it's hard to see.

etc etc...

As a very quick test I tuned for maximum Power out on my external meter (which is fine by the way, I tested it on another radio), and again it will give me around 55W (when lucky)... the IP reading around 80mA - 110mA now (which is more

in line having swapped the 10K resistor for 4.7K).

When I get time later tonight, I will have to do some voltage readings (Again) :(- Any other suggestions?

Thanks
Chris Parnell

31401. Re: Transmit has died

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-05-19 13:21:25 UTC
From: w5rkl
Topic: 31320 Message: 31401

The relay Terry is referring to is on the AF Unit board. This relay controls quite a few circuits when switching between receive and transmit. This is the same relay used in the TS-530 on the IF Unit board plus the TS-120 (there are 2 of them), TS-130 (also 2 of them), and other Kenwood transceivers.

While "very carefully" cleaning this relay may "appear" to fix any problems the relay has caused, the fix is quite often short lived. Therefore, if you suspect this relay is bad, replace it, don't waste your time cleaning it.

A few of the circuits the AF Unit relay controls/switches (receive to transmit and vice verse) are:

Meter from displaying S Units in receive to displaying what ever the meter switch is set to.

Bias levels to the driver tube (DRB), Transmit Bias (TB) to the IF Unit, and bias voltage level to both final tubes.

73s
Mike

31402. Re: Kenwood Hybrids net ...When, Where?

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-05-20 00:00:30 UTC
From: roberteleazer@rocketmail.com
Topic: 31206 Message: 31402

The situation on the Kenwood Hybrids Net is that a bunch of people would like to have one but there is a separate Yahoo group, Kenwood QSO set up to handle such coordination. And the Kenwwod QSO Group, while requiring memebrship in this group, is so hard to find on Yahoo that you seem to be only able to find it by first going to some kind of "microphone" group and linking to it from there.

And the last time anyone posted anything on the Kenwood QSO group was a couple of years ago, which I guess explains why we are talking about it here.

The summary of possible bands seems to be:

80M: Too local

40M: Possible

20M: Too crowded and often not good at night

15M: Possibly good if the members of the group are all either on the East Coast of the U.S. or in eastern Europe.

10M: Too sporatic.

So I guess we are down to 40M being it. Sounds Okay to me. We need a net control station or two with a good antenna system and located in a central location.

There are a few of us that get together on 20 during the week and we never have had a real problem with the band being too crowded.
I suggest something around 14.243 or so maybe even 14.237 is also good.
The Frequency we have been meeting on (a few of us) is 14.218 but this is outside the band for General class. We all started off running Hybrids, but rigs have changed in the last few years. Some run Collins now, some Kenwood's and some run Yaesu's

Robert,

I have been over to the QSO group and there is about 10 new members but not much traffic. I can provide a link if anyone is interested; I did post it a couple of days ago but will post it again if needed. 40m sounds good to me. I am in Florida so I am not in a good location for net control; and I have never been net control so I would not be a good candidate. I'm sure if you name a frequency and a time you will have a lot of people show up.

31405. TS-520 Output

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-05-20 02:14:32 UTC
From: ki4ax
Topic: 7262 Message: 31405

Mike,

When I tune my TS-520 for 40m (on a dipole cut to resonance)I get about 120w out. I did not note the exact Ip but the rig usually runs about 250ma. Do you think this is pushing the rig too hard? And if I want to cut back on the output, to take it easy on the final section, would I make that adjustment using the LOAD control to take some of the load off? Or should I cut back on the MIC gain control? I value your opinion and would greatly appreciate your comments.

Thanks,

Dan KI4AX

If you're looking for the plug to go into it, K4EAA stocks those.

If you're looking for the jack itself -- I expect you'll have to pick one up wherever you can find one.

If you tune up in the "tune" position, you only have about half power because the screen voltage is reduced in that mode. complete your tune and load adjustment in the "CW"mode.
This is where you may see full recomended power and plate current readings.

Good call Mike, I will double check later today.

I am pretty certain I was in either Tune or CW though when I measured the voltages, but I may be wrong.

Cheers
Chris

Hello Dan,

Tuning up in TUNE then switching to CW, you would use the CAR control to adjust power output.

The 520 is rated at 160 watts DC input in CW mode, not 180 watts.

The 520 has a DC input power rating of 160 watts. The final amplifier has an efficiency rating of 55% which means normal power output in CW mode with 160 watts DC input will be 88 watts (160 - 45 % = 88 watts). When you tune the transmitter and the IP meter shows 250ma and output is 125 watts, adjust the CAR control for an IP indication of 200ma. With an IP indication of 200ma the HV will be approximately 800VDC which will result in a DC input power of 160 watts in CW mode. This is the normal power rating for the 520 in CW mode. Once you have tuned the 520 up to these current and HV levels, switching to sideband will produce approximately 200 watts PEP input, the normal sideband input power rating. You don't have to readjust anything.

Yes, the MIC gain, along with any ALC produced during sideband transmissions, controls power output in USB and LSB modes. If you follow the steps I indicated above you will be operating your 520 within the factory specs and you will not be overloading/pushing the final amplifier excessive. As I have said quite often, for a clean transmit signal in sideband, adjust the MIC gain while talking 1 to 2 inches from the microphone in a normal voice level so the ALC meter just starts to flicker above zero. This MIC gain setting will produces a very clean sideband transmission. It's not how LOUD you sound but how clean your transmit signal is. There are many stations that talk loud into the microphone, have the mic gain set too high or their external audio processing equipment is set so the ALC peaks well above middle and many times exceeds the top of the ALC scale just so they sound LOUD at the receiving end. Not only is that very poor operating practice but it causes adjacent frequency interference and pushes the final amplifier too hard. I hear a lot of those stations on 80 and 40 meters, just tune around and you'll hear them.

Remember, ALC does not cause your power output to increase. In fact, it's the opposite, power output is reduced when ALC is produced in sideband transmission.

As for adjusting the LOAD control to reduce power output, I do not recommend doing that. Tune for maximum power output as I stated above then reduce power using the CAR control for 200ma of IP current. Then adjust the MIC gain as I indicated above and you will be fine.

73s
Mike

>Hi Chris-- Before you attempt to clean RL-1 or replace it take a look at Connector 5 on the IF board. It is a 3 terminal connector about 3/4 way toward the front of board right in front of ALC zero pot VR6. With meter in ALC position, rig in tune, flip to send and watch ALC meter and your wattmeter as you gently wiggle and/or tap on this connector. This connector works in concert with RL-1 and applies 9v on pin TB (transmit bias) that turns FETs Q28 and Q29 on and produces Transmit IF (TIF). No TIF means no drive, no ALC indication on meter, and no RF output. I have found that the connectors are a weak point. The connector socket mounted on the board can have bad connections due to cracked/lifted foils or poor factory soldering. Plugging and un-plugging connector typically wont fix this problem. I can give you some tips how to resolder if you find it is the problem. 73s Terry K9TW

> The relay Terry is referring to is on the AF Unit board. This relay controls quite a few circuits when switching between receive and transmit. This is the same relay used in the TS-530 on the IF Unit board plus the TS-120 (there are 2 of them), TS-130 (also 2 of them), and other Kenwood transceivers.
>
> While "very carefully" cleaning this relay may "appear" to fix any problems the relay has caused, the fix is quite often short lived. Therefore, if you suspect this relay is bad, replace it, don't waste your time cleaning it.

I've never been net controller before also. I'm just going to call CQ 20MAY11 on 14.250 +/- and see if I can contact anyone. Calling it a net at this stage would be a stretch. :) It seems a good place to start. Evening would work other times, I can't be sure I"m going to be home this Friday. Perhaps we can try Saturday Even as well.
How does CQ KenwoodQSO sound to everyone. I'll repost this on the KenwoodQSO group as well.

I started a thread on KenwoodQSO group. I will be calling CQ Friday May 20,2011 at 9AM-9:45 Central (14:00 UTC) on or about 14.250 for tubes and hybrids. Not exactly a net operation but a start.

Mike, Thanks for the great info. I will try this next time I tune the rig; I certainly don't want to cause any damage to the finals. I have another set ready to go in when the existing ones decide to go out... so far I don't see any indication that I need to do that yet. If I take it easy with the existing ones perhaps they will last another 30 years.

Thanks again.

Dan KI4AX

> Tuning up in TUNE then switching to CW, you would use the CAR control to adjust power output.
>
> The 520 is rated at 160 watts DC input in CW mode, not 180 watts.
>
> The 520 has a DC input power rating of 160 watts. The final amplifier has an efficiency rating of 55% which means normal power output in CW mode with 160 watts DC input will be 88 watts (160 - 45 % = 88 watts). When you tune the transmitter and the IP meter shows 250ma and output is 125 watts, adjust the CAR control for an IP indication of 200ma. With an IP indication of 200ma the HV will be approximately 800VDC which will result in a DC input power of 160 watts in CW mode. This is the normal power rating for the 520 in CW mode. Once you have tuned the 520 up to these current and HV levels, switching to sideband will produce approximately 200 watts PEP input, the normal sideband input power rating. You don't have to readjust anything.
>
> Yes, the MIC gain, along with any ALC produced during sideband transmissions, controls power output in USB and LSB modes. If you follow the steps I indicated above you will be operating your 520 within the factory specs and you will not be overloading/pushing the final amplifier excessive. As I have said quite often, for a clean transmit signal in sideband, adjust the MIC gain while talking 1 to 2 inches from the microphone in a normal voice level so the ALC meter just starts to flicker above zero. This MIC gain setting will produces a very clean sideband transmission. It's not how LOUD you sound but how clean your transmit signal is. There are many stations that talk loud into the microphone, have the mic gain set too high or their external audio processing equipment is set so the ALC peaks well above middle and many times exceeds the top of the ALC scale just so they sound LOUD at the receiving end. Not only is that very poor operating practice but it causes adjacent frequency interference and pushes the final amplifier too hard. I hear a lot of those stations on 80 and 40 meters, just tune around and you'll hear them.
>
> Remember, ALC does not cause your power output to increase. In fact, it's the opposite, power output is reduced when ALC is produced in sideband transmission.
>
> As for adjusting the LOAD control to reduce power output, I do not recommend doing that.

Tune for maximum power output as I stated above then reduce power using the CAR control for 200ma of IP current. Then adjust the MIC gain as I indicated above and you will be fine.

And if I want to cut back on the output, to take it easy on the final section, would I make that adjustment using the LOAD control to take some of the load off? Or should I cut back on the MIC gain control? I value your opinion and would greatly appreciate your comments.

31420. FS: TS-830S Gold Edition

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-05-20 22:55:51 UTC
From: KA5TRO
Topic: 31420 Message: 31420

Bought this a while back as part of an SK estate locally (northeastern Oklahoma). I already have a TS-830S Gold (as well as a TS-530SP, which may be offered up soon as well) so this is surplus to my needs. I bought the lot primarily to get a couple of other pieces of gear (along with this, too, to be fair), and I want to pass this along to someone who will appreciate it.

TS-830S Gold Edition. Cosmetically very good to excellent-minus. Minor scratching on case and minor finger "shine" wear on faceplate -- no scratching on faceplate at all. I've cleaned it up and tested it and it has full output on all bands. Includes extension feet. I have the original manual as well (though the SK taped the spine with duct tape and it's in fair condition overall). I'll include a 'generic' hand mike correctly wired. Sorry, I don't have the original mike.

Only problem with it right now is that I broke the plate pointer in half when I was cleaning it up. I'm expecting a replacement from KE5FTF when he gets back from Okinawa. I'll send that after the fact if need be.

Photos available on request.

Asking $400 shipped in CONUS. As this is a heavy rig, shipping will not be inexpensive, so I think this is a fair price.

Contact me off-list at [mycallsign]@... with questions, offers, etc. I could be persuaded to trade this for the right trade offer. Offering it to this group first before taking it to QTH/QRZ/eHam.

Thanks for looking.

Already sold to WB7UQU! Must have priced it too low! :-D Thanks for the inquiries -- there were several.

Now, I *also* have an SP-230 available. WB7UQU didn't want it. It's in similar condition -- very good to excellent-minus. Mostly finger "shine" on the front. No connecting cable (1/8" phone to RCA). Includes extension feet.

Asking $65 shipped. Same contact. Thanks.

ktwhy2003,

In theory, any change in frequency other than the one that you "tuned-up on" requires a change in the, "drive," "load," and "plate" adjustments. If it is minor...it is just a "few tweaks," and can be done quickly. If you are adjusting while "on air,"....inquire if freq. is busy... announce your call...and that your are testing...if done right...10-15 seconds.....

ok,, kind of what I though, I've been dialing around 20m all afternoon, and have gotten on the air.. listening to the net on 14.3 and hopping around. But being new to hybrids the whole process makes me nervous (not got for some body that suffers from panic attacks as it is).

I was using a TS-50S on loan to me, and with my TS-830S is a lot nicer rig, I do appreciate the simplicity of solid state also.

Thanks Gordon for the QSO today.

It was good hearing you on the air, and working 830 to 830 made it great!!

I heard the qrm and figured you might be up or down a few.

Mike,

In the post below you said that "Once you have tuned the 520 up to these current and HV levels, switching to sideband will produce approximately 200 watts PEP input, the normal sideband input power rating." Then with an efficiency rating of 55%, for the final amplifier stage, and an input of 200 watts I should be producing about 110 watts on ssb... that is if I modulated the signal with something producing a duty cycle close to 100%. This also means, if I am understand correctly, that out of the 200 watts being input to the final section 90 watts is being dissapated as heat? I'm I understanding this correctly? And if that is correct do you know what time function is involved? Is it 90 watts per hour? Just trying to understand how much heat the rig should be generating. I assume that being tube finals with a cooling fan there should be quite a bit of heat being generated during use. In other words, during use like rag chewing, it should be producing enough heat to get pretty warm but not what you would consider hot... right?

>
> The 520 is rated at 160 watts DC input in CW mode, not 180 watts.
>
> The 520 has a DC input power rating of 160 watts. The final amplifier has an efficiency rating of 55% which means normal power output in CW mode with 160 watts DC input will be 88 watts (160 - 45 % = 88 watts). When you tune the transmitter and the IP meter shows 250ma and output is 125 watts, adjust the CAR control for an IP indication of 200ma. With an IP indication of 200ma the HV will be approximately 800VDC which will result in a DC input power of 160 watts in CW mode. This is the normal power rating for the 520 in CW mode. Once you have tuned the 520 up to these current and HV levels, switching to sideband will produce approximately 200 watts PEP input, the normal sideband input power rating. You don't have to readjust anything.
>
> Yes, the MIC gain, along with any ALC produced during sideband transmissions, controls power output in USB and LSB modes. If you follow the steps I indicated above you will be operating your 520 within the factory specs and you will not be overloading/pushing the final amplifier excessive. As I have said quite often, for a clean transmit signal in sideband, adjust the MIC gain while talking 1 to 2 inches from the microphone in a normal voice level so the ALC meter just starts to flicker above zero. This MIC gain setting will produces a very clean sideband transmission. It's not how LOUD you sound but how clean your transmit signal is. There are many stations that talk loud into the microphone, have the mic gain set too high or their external audio processing equipment is set so the ALC peaks well above middle and many times exceeds the top of the ALC scale just so they sound LOUD

at the receiving end. Not only is that very poor operating practice but it causes adjacent frequency interference and pushes the final amplifier too hard. I hear a lot of those stations on 80 and 40 meters, just tune around and you'll hear them.
>
> Remember, ALC does not cause your power output to increase. In fact, it's the opposite, power output is reduced when ALC is produced in sideband transmission.
>
> As for adjusting the LOAD control to reduce power output, I do not recommend doing that. Tune for maximum power output as I stated above then reduce power using the CAR control for 200ma of IP current. Then adjust the MIC gain as I indicated above and you will be fine.

And if I want to cut back on the output, to take it easy on the final section, would I make that adjustment using the LOAD control to take some of the load off? Or should I cut back on the MIC gain control? I value your opinion and would greatly appreciate your comments.

Hi Dan,

The glass envelopes get hot enough to burn your fingers and leave blisters if you could touch them. Don't ask me how I know this <evil grin>. You could keep your coffee hot by setting your coffee mug above the finals. But don't set your coffee mug there - eventually you'll spill coffee in there - *BAD*. I haven't actually spilled coffee in mine because I thought that one through and I don't set my coffee there.

Your understanding of the power being dissipated as heat is essentially correct.

Hey Bill,

Thanks for the reply. No I would never put coffee up there any way... you don't have to worry about that. Well, I have had this rig since the 80's but have not had it on the air for a long time. The last entry in my log book was 21 years ago and as a result, I don't remember how much heat the thing produced. Also, because the rig is 30 plus years old, I want to make sure I am taking it easy and not trying to burn things up if you know what I mean. I must have done a pretty good job and not pushed it too hard 20 years ago because the final section and amplifier tubes seem to be in pretty good working order for being 30+ years old. I worked a few stations last night and she got pretty warm but no where near hot enough to cook eggs or any thing like that... it might have kept my coffee warm though.

Thansk again...

Dan and others,

The final amplifier's in all of the Kenwood hybrids, as well as many other tube based transceiver final amplifiers, operate in Class AB1. The typical efficiency rating of these final amplifiers is 55% which mean 45% of power is loss to heat and other factors such as resistance (reactance whether inductive or capacitive).

To determine the approximate efficiency of the final amplifier, the following formula is used

Ef% = Po / Pin

where "Ef%" is the amplifier's efficiency percentage rating, "Po" is power output and "Pin" is power input.

For example, the 520 has an DC input power rating of 160 watts in CW mode. That typically results in 88 watts output from a properly tuned transmitter. So what is the efficiency percentage rating?

Using the above formula, it's 55%

Ef% = 88 / 160 = 55%

The same applies to sideband. If PEP input power is 200 watts and the output power is 110 watts PEP, the amplifier's efficiency rating is still "55%"

110 / 200 = 55%

The typical IP current in CW mode is 200ma and HV is approximately 800VDC for 160 watt DC input, the typical CW power input rating of the 520. To determine the DC input power simply multiply the final amplifier's HV at full output times the IP current.

DCPin = IP x HV

.200 x 800 = 160 (DC watts input).

"DCPin" is the DC Power Input in CW mode

"IP" is the combination of the final amplifier's screen and plate current.

"HV" is the DC HV at the plates of the final tubes at 160 watts DC input.

You don't need a watt meter to determine what the approximate power output is. All you need is the HV and plate current then use the formula presented above.

I hope this helps to answer your question(s) Dan.

> > The 520 has a DC input power rating of 160 watts. The final amplifier has an efficiency rating of 55% which means normal power output in CW mode with 160 watts DC input will be 88 watts (160 - 45 % = 88 watts). When you tune the transmitter and the IP meter shows 250ma and output is 125 watts, adjust the CAR control for an IP indication of 200ma. With an IP indication of 200ma the HV will be approximately 800VDC which will result in a DC input power of 160 watts in CW mode. This is the normal power rating for the 520 in CW mode. Once you have tuned the 520 up to these current and HV levels, switching to sideband will produce approximately 200 watts PEP input, the normal sideband input power rating. You don't have to readjust anything.
> >
> > Yes, the MIC gain, along with any ALC produced during sideband transmissions, controls power output in USB and LSB modes. If you follow the steps I indicated above you will be operating your 520 within the factory specs and you will not be overloading/pushing the final amplifier excessive. As I have said quite often, for a clean transmit signal in sideband, adjust the MIC gain while talking 1 to 2 inches from the microphone in a normal voice level so the ALC meter just starts to flicker above zero. This MIC gain setting will produces a very clean sideband transmission. It's not how LOUD you sound but how clean your

transmit signal is. There are many stations that talk loud into the microphone, have the mic gain set too high or their external audio processing equipment is set so the ALC peaks well above middle and many times exceeds the top of the ALC scale just so they sound LOUD at the receiving end. Not only is that very poor operating practice but it causes adjacent frequency interference and pushes the final amplifier too hard. I hear a lot of those stations on 80 and 40 meters, just tune around and you'll hear them.
> >
> > Remember, ALC does not cause your power output to increase. In fact, it's the opposite, power output is reduced when ALC is produced in sideband transmission.
> >
> > As for adjusting the LOAD control to reduce power output, I do not recommend doing that. Tune for maximum power output as I stated above then reduce power using the CAR control for 200ma of IP current. Then adjust the MIC gain as I indicated above and you will be fine.

Do you think this is pushing the rig too hard? And if I want to cut back on the output, to take it easy on the final section, would I make that adjustment using the LOAD control to take some of the load off? Or should I cut back on the MIC gain control? I value your opinion and would greatly appreciate your comments.

I agree with Brad. The first thing you should do, before swapping any tubes, is to take voltage measurements. Quite often, loss of power output, as in your case Jess, is not caused by bad tubes but rather a failure in a circuit component(s).

Hi all,
I have just acquired a very nice TS520SE in good condition and working order.
The problem is that after tuning using correct procedure, if I adjust mic gain to give around 80-90 watts peak when I switch meter to ALC it is pegging the meter right across.
If I reduce mic gain to around 3 the ALC is within limits but peak power is only around 40 watts, stations I have worked say that I sound ok at 90 watt level.
The mic I got with the rig appears to be a pace mic (possibly a CB mic) so I wonder if this is causing the problem or is some adjustment needed.

Please follow the instructions in the manual concerning ALC levels. (you do have the owners manual, don't you?)

The human voice's average power is about 25-30 % of its peak power. The meters on the 520 read AVERAGE power. If you can read 100 watts in CW mode, you should only be driving the rig to 25-30 watts in SSB mode. This is perfectly normal. Any more output than this is just adding distortion to your signal.

I don't know who is telling you that you sound OK at 90 watt level, but I would be willing to bet that they do not know how good a 520 CAN sound if it is not being over-driven.

The ALC above about 1/3rd scale or less is TOO MUCH .

This question comes up so often, that I cannot understand WHY it isn't taught in every license class that is conducted.

73, Jim

John,

Why did you turn the MIC gain up until the watt meter displayed "90 watts"? Were you told to do that or was it because you thought the watt meter should show 90 watts? Also, what make and model watt meter are you using?

I agree with Jim, you have the MIC gain set way too high. The ALC meter should NEVER go full scale! If someone told you to turn the MIC gain up so the watt meter displayed 90 watts then they mislead you!

After tuning the 520SE up properly (follow the 520SE operator's manual), set the meter switch to ALC. Set the MIC gain fully CCW (lowest setting) then press the PTT button. Speak into the microphone from a distance of 1 to 2 inches in a normal voice level and advance the MIC gain until the ALC meter just barely flicker above zero on voice peaks. At this point stop adjusting the MIC gain, the 520SE is producing maximum power output with very little, if any, distortion. The watt meter will more than likely display 20 to 30 watts peak output which is "normal".

One way to confirm you are 'pushing power' is to carefully watch the brightness of the meter and dial lamps.

Despite the RF indication seeming to be low, I'll bet you can see the brightness of those lams dimming slightly on voice peaks - this is proof (if you needed it) that the rig is actually drawing, and therefore outputting, power.

As already said, set the mic gain so you can just see some ALC action - this is ample and you will be heard! Don't expect to see a continuous power indication as voices don't behave that way unless female, and screeching...

Hi Mike and Jim,
Thanks very much for the advice, I have tried the radio as you suggest and have had some good contacts this evening, I have the manual and follow the tune up procedure.
One thing I have just noticed is that I tried the radio on different bands, it was fine on 80m, 40m and 20m, I found that on 20m I had to back the mic gain off more than the lower bands.
I tried to tune it on 28.5mhz and found that I couldn't peak the ALC during the initial tune up even with the carrier level at maximum, I dipped the plate current and tuned with plate and load and could only get about 30w in the final tune up in CW position.
I think I read somewhere that this could be a driver tube problem ?.
What do you think.
Many thanks again John M0JVW

Hi John,

There has been some evidence that driver tubes, when going soft, will produce lower drive to the finals at higher frequencies.

An easy test of the driver tube is to watch the ALC indication during TUNE mode. When peaking ALC, in TUNE mode, a weak driver tube will have a tendency to show a peak ALC meter indication but after a very short period, possibly a few seconds or so, the ALC meter indication will start to drop back towards zero. A good driver tube will produce a solid and stable ALC peak indication on all bands during tune up. A good driver tube will produce more than enough RF drive to the final tubes to results in a full scale ALC indication during tune up.

Hi Brian,

Gordon, N6WK, is one of the Moderators of this group. I can't and won't speak for Gordon regarding work on your 520. Therefore, you would have to drop him an e-mail and ask him about working on your 520. Gordon has a website, www.n6wk.com, that contains a lot of valuable information on the various Kenwood hybrid rigs and microphones etc.

Hello again to all. 820 is working great except for one issue. I tried using the remote socket to key my amp but it won' t work....I get a closed contact on the plug when I key up but it won' t trigger the amp. The amp has a 24v relay which is powered by a small 1a power supply in the amp. This setup works great with my Drakes which uses the same basic setup (small relay).. I tried cleaning the relay in 820 but no go...any ideas....Bill

sent via samsung android..

Hi Mike,
I tried what you suggest and the needle seems to hold ok in bands up to 28mz.
You can get alc on 28 mhz position (with increased carrier level) but when I try 28.5mhz there is no drive although I can get some power out at this frequency.
Thanks again
John

Hi John,

Many hams tend to look at the absence of ALC indication during tune up as loss of RF drive and that's not true, especially if there is plenty of drive/ALC indication on the lower bands and tuning up in CW mode on the higher bands produces RF output.

ALC occurs ONLY when a portion of the RF driving signal's Positive Sine Wave is at a level that causes the grids of the final tubes to swing positive. If the RF driving signal is not at that level during the positive segment of the RF sine wave that results in the grids of the final tubes to swing positive then there will be no ALC indication.

When the grids of the final tubes swing positive, a current exits between the final tube's cathode and grid. When this occurs, a voltage is produced due to a "difference in potential" existing between the ALC transistor's "emitter" and "base". This difference in potential results in the ALC transistor's collector voltage to change. The change in the ALC transistor's collector voltage is the actual ALC voltage. If there is no grid current flowing then there will be no difference in potential between the ALC transistor's emitter and Base and the ALC transistor's collector voltage will remain the same, no ALC is produced. This does NOT mean there is a loss of RF drive. It simply means the level of RF drive to the final amplifier is not at a level that causes the grids of the final tubes to swing positive.

As I said, there is evidence that a weak driver tube can result in lower RF output on higher band(s) then lower bands.

Bill,

You say you get a "closed circuit" when connecting the amplifier to the 820's 8 pin octal socket. What pins are you using on the 820's 8 pin octal socket?

Pins 3 and 4 should, in receive, be "open" but "closed" in transmit.

If you don't see this happening then you have it wired wrong. You also could have bad connections in the 8 pin plug. I've seen this happen quite often, even if you are using the correct pins, 3 and 4.

I typed the wrong pins.

The rear 8 pin octal socket pins "5" and "4" should be used to key the relay, NOT pins "3" and "4".

Connect pin "5" to the amplifier's hot relay terminal and pin "4" to the amplifier's chassis.

Mike, I am using pins 4 and 5, which are shown in the manual as the open contact. I get 4 and 5 to close, according to my meter, but it is not closing the relay in the amp, maybe a high resistance in the contact under a heavier load than an ohm meter....I just put together a transistor interface to drive the relay in the amp..we will see if that works...73

Bill,

I had a similar problem with my Drake T4XB transmitter. I had the right amplifier relay connections but the amplifier relay simply would not activate in transmit. I even went as far as manually activating the relay armature and checking the rear pins to ensure the closure was occurring which it was. But, when I plugged the 12 pin "female" side of the power connector into the male pins it wouldn't work, no closure even when manually activating the relay armature.

I found the problem to be the "female" pins on the rear of the transmitter were not making contact with the "male" pins. Cleaning the male pins with contact cleaner and an old tooth brush then inserting the female plug a number of times with the male pins wet with contact cleaner, fixed the problem.

You might also check to ensure the solder connections between the wires and the pins is good. Continuity from the male pin, not the wire sticking out of the male pin, is good to the end of the wire that connects to the amplifier's relay socket. I have seen bad soldering that appears to be good (visually) but in reality it was not good.

Hi Kent,

The main power switch and heater switch are both the same, part number S59-2020-05.

You might write Bob Mansker, ke5ftf at mail.com and ask him for a replacement.

31470. Blowing the cathode resitors with intermittent monotony - TS-820s

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-05-25 01:46:42 UTC
From: Robin
Topic: 31470 Message: 31470

Hi, I seem to keep blowing the cathode resistors with some monotony on a TS-820s I am restoring and for no reason I can find. I have checked all voltages under both RX and TX (80W output or so, measured two different ways CW) and B+ is 850V (I have checked and replaced the HV resistors in the HV unit to ±1%), C- is correct and only droops a couple of volts under TX, and SG at 257V on RX, 180V - 130V on SG depending on transmit mode (FSK, TUNE, CW). SG voltage is high, but the SG current is less than 20mA, so within bounds. Power output does drop after a second or so from 100W to 80W on CW, which makes me suspicious. So, if the voltages and currents are within ballpark, this only leaves the tubes: can soft finals contribute to blowing the cathode resistors? I can't see a mechanism that would do this. Reports from local stations tell me that my SSB sigs sound great, so I can assume that everything before the driver is good. What gives?

The Kenwood newsletters were published by Rob, N8RT. Go here for more information: http://n8rt.com/ About 3/4 down the page, it indicates that International Radio (INRAD) was selling back issues of the newsletters. Not sure if the new INRAD owners are doing the same or whether Rob still retains copyright ownership of the newsletters. I think I have about 5 to 8 years worth of newsletters.

Robin,

I highly suspect the finals. Have they been changed and now you're blowing the R's? It has been my personal experience on both an 820 and 830 that I was not as lucky as you...as soon as I turned on the heater...zap/pop...I had just put in new 6146B's...China's finest...they were the cause of the problem. Check your Ip to see if it drops after you "key-down" in CW...the Ip should hold steady...if not..your driver or finals may be giving up the ghost...also how's the "dip" in CW mode? If it is broad and shallow this usually indicates driver going bad. Good luck.....

Pete--Do you know if anyone ever published an index? I seem to recall that Rob owned INRAD and sold it? Maybe I will contact him and see what he has available. I will look at the INRAD site. If they are selling back issues maybe they have an index?

I am only interested in the years/issues that address our hybrids. Especially interested in any articles on rig maintenance and alignment. I was hoping to find an article on the VBT-1 test jig. I would like to find out if a schematic is available for it. I wrote Kenwood (california) and they didnt know what I was talking about. Perhaps there are articles on alternate ways to perform some of the alignment steps in the TS-830S service manual? In addition to the language translation problems in this manual there are some steps that need amplification/clarification or just cant be performed as written. I wonder what it would take to get the back issues on Gordons site? Terry

I even went as far as manually activating the relay armature and checking the rear pins to ensure the closure was occurring which it was. But, when I plugged the 12 pin "female" side of the power connector into the male pins it wouldn't work, no closure even when manually activating the relay armature.
>
> I found the problem to be the "female" pins on the rear of the transmitter were not making contact with the "male" pins. Cleaning the male pins with contact cleaner and an old tooth brush then inserting the female plug a number of times with the male pins wet with contact cleaner, fixed the problem.
>
> You might also check to ensure the solder connections between the wires and the pins is good. Continuity from the male pin, not the wire sticking out of the male pin, is good to the end of the wire that connects to the amplifier's relay socket. I have seen bad soldering that appears to be good (visually) but in reality it was not good.

31477. relay problems in 599 twins

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-05-25 15:41:28 UTC
From: Bill
Topic: 31477 Message: 31477

Hi,

My Twins are getting long in the tooth and have made lots of QSOs over the years. That includes being dragged out to Field Day numerous times. The transmitter develops ALC voltage okay but it does not get applied to control the output. That particular detail involves the T/R relay which has clicked in and out how many dozen times now?

The receiver has been developing some intermittent woes, too, and you might know there is an identical relay in there that has clicked in and out just exactly as many times as the one in the transmitter. New relays are ordered. I will probably have some leftover issues after they are installed but they are both obviously wearing out. There is no point looking further until the relay problems are removed. I'll post results when they are in place.

My QRP operation has been successful even without the ALC trick working. I carefully aligned everything except the bandpass filter (~8 MHz) and the T-599 behaves well and will dial down to ~1 or 2 watts with just the "Carrier" control (CW). I have been running it just under 5 watts. At the other end of the range I can still get full power output.

73,

Bill KU8H

31478. 530 s intermitten audio hum

Hi Gang, I'm sure someone here can answer my question. I have an intermittent hum on my transmit audio. Ken's website says that if you have pin 4 connected on the mic plug that you will get a hum.Should there not be anything connected here. The manual seems to show the 2 mic element wires connected to 1 and 4 with a ground connected to 4 also? How should I wire this connector. I'm using a telex/turner RK 56 hand mic if anyone is familiar with them. I saw an ad in an old cq mag of a heil HMM hand mic that I think may be a better mic but it's no longer in production. I also have an audio comm boomset that worked really great on a ten tec rig that I had to sell but I believe it has an electret element is there any way I can make this work on my 530? Thanks in advance. Richard KM5WX

Every year I think in the January issue, an index was printed for all the articles of the previous year. There were also supplemental collections of articles for specific rigs that appeared on the market in the 90's. I think I still have a TS-430S collection. If you read Rob's blog at the link I provided, you'll see the history of INRAD. From what I remember without digging them up, there were lots of hinks, mods, tweaks, regurgitation of old problems, kenwood service addenda, etc. Most were submitted by members but, from I remember, generally there was no formal testing to validate the article(s). Over the years, a lot of this same info, has found its way to specific Internet sites that cater to specific models or model families. I seriously doubt you'll find something there that hasn't already been covered somewhere on someone's Internet site in one form or another.

Richard,

I think you may have mis-read Ken's info. If this is Kenwood MC-50 or other similar mic...check the following: (the mic base end has 5 pins, the radio end has 4)

Base end pin #1 (yellow wire) to radio end pin #1
Base end pin #2 (shield) to radio end pin #2
Base end pin #3 NOT USED
Base end pin #4 (red wire) to radio end pin #3
Base end pin #5 shield to radio end pin #4

You may have an intermittent problem in the cord. Go to Ken's web site, look under "Large Format Schematics" and go way down to the bottom...you will see the wiring diagram for the pins

31481. TS830s _ plate current way too high !!

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-05-25 17:56:04 UTC
From: Will
Topic: 31481 Message: 31481

Guys, a chum of mine recently managed to fry the output stage of his 830s by simply not having a load on the antenna output. Please dont ask as I have absolutely no idea !! Guess he was plain dumb !! The 6146b bottles were totally destroyed too. Now, I have managed to obtain a replacemement choke, (his original was fried to a crisp) which sits between the bottles and have hooked everything up and made a brief attempt at getting something out of this old lady once more. Problem: In all output modes including TUNE, the plate current reading is virtually full scale and even by adjusting the bias on the rear of the rig, it hardly reduces at all. I have checked out the solder joints in and around the pa bottles (which incidently are brand new) and cannot come up with a reasonable theory as to why this should be happening. The 12by7a driver is also new. The HV reading is a little over 900 volts. Clearly something appears to be drawing full plate current and even adjustments on LOAD, PLATE and DRIVE have no impact at all. I have also made an attempt to alter the bias potentiometer for a reduced reading on the back of the rig but this only invites a very minor reduction in current reading. Any thoughts.......Will

Will,

Check the value of the 4 (four) 20 ohm resistors on the final board. The board does not have to be removed to do this. It will help to find an X-RAY view of the board(try n6wk.com) and look in the service manual to locate the R's in question. They should measure about 5 (five) ohms to ground +/- tolerance. Simple first step

Maybe the coupling condensor between the 12BY7A and the finals is bad and you have positive grid voltage.

Just a tought,

Ok Pete--I suspect you are correct. I know most if not all the service bulletins are on line and I have copy of the Survivors Guide. Still would be fun to look at the Hints, Tweaks etc. If nothing else the history would be fun. Yes--there is some risk in performing suggestions in unvalidated technical articles. I wrote INRAD today so will see what they say. I specifically asked about indexes. Appreciate your insights. Terry

31485. TS-820S Display Off Freq.

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-05-25 20:17:37 UTC

Hello to all,

I'm new to the group,...and have recently obtained a TS-820S from an estate. This is my first experience with the "Hybrids" so please bear with my "green-ness".

This radio like many that have been "sitting around" for years, has a few issues that need to be resolved. The first problem I need to take care of is the display. For some reason it is showing a frequency that is always / exactly 5Mhz. higher than the actual operating freq. It is happening on all the bands. For example....40M display reads 12.xxx, 20M reads 19.xxx, 15M reads 26.xxx. etc. The khz. portion is always correct but the Mhz. is always 5Mhz higher. The actual frequency (being received in this case) is correct if I mentally subtract 5Mhz. from the display. On occasion, if I put pressure on the VFO knob a bit ,...the display would correctly display the proper freq., but then revert back to the "5-up" display.

I have searched a bit through the Msgs. here but haven't found anything specifically regarding this problem. Seems like there are a number of issues with poor / loose ground connections / screws related to the display & VFO to deal with, So my first question for the group is ,...Has anyone encountered this before,? Any thoughts on the best route to follow to try to resolve the problem ?

Again, being new to the "Hybrids" and their restoration, and with all the mentioned "grounding" issues...Is there a recommended "To-Do" list I should follow to help alleviate those ground related problems? Such as "Make sure you clean,...tightened,...resolder, on this module"...etc.

Sorry for the long post,...

Thanks in advance for any thoughts / recommendations,
Carl

Will, I have had this twice in the past fee weeks, most likely the cathode resistors are blown. Mine read around 7K to ground when it read full deflection in IP mode.

Swapped them out and all good now.

Check these first Will Change them if needed for 4x new 20 Ohm 1/2 watt resistors.

Cheers

Hi Carl,

I recommend cleaning the Display Unit plugs on the bottom (top and bottom covers need to be removed and the 820 turned upside down) first.

In addition, clean the IF Unit plugs and pins.

Once these are done check for proper operation.

It is also possible that the 2 PC boards inside the Display Unit have connection problems (corroded/dirty fixed pins inside the Display Unit) that may also need cleaning.

If you do not have the operator and service manuals for the 820 then I recommend you download them from Gordon's website

Topic: 31485 Message: 31489

Carl:

Mike's comments about cleaning the display unit contacts are excellent, as usual.

What I would suggest is that since the VFO operates in the 5 MHZ range the tuning cap is shorting out and causing the frequency to be off. My TS-820S did this when I first got it, jumping by 5 MHZ at spots on the dial. The fact that you can wiggle the knob and make it come and go tends to confirm this as a possibility.

I recommend you do one of the following:

1. Spray some CRC Lectro contact cleaner inside the hole in the VFO can, tunr it upside doan and let it run out, and hope that cleans things up. This would be called "Spray and Pray." You can get the CRC stuff at Ace Hardware, usually.

2. Take the VFO out of the transceiver (there is an illustrated procedure for doing this online), take the can off, clean the tuning cap with first all over with CRC Lectro and then the bearing points with Deoxit and then lube the bearings with a wee bit of LPS-1, applied with a Q-tip or artist's brush. If you do not have access to deoxit (Radio Shack usually has it at a merely ridiculous price) you might just try the CRC and LPS-1.

Good Luck!

Hi Guys,

Here in VK the newsletter came from Kenwood (Sydney) Australia, every three months. It had a lot of Kenwood advertising and lots of specials/discounts for Kenwood User members, but when Kenwood Australia went, so did the club. It covered things along the lines of adding an 8.83Mhz IF output to the TS 530 to enable the SM220 BS8 to be used, adding a meter light to the AT230 via the TS830/530 series. Circuit updates and technical related issues all tried, tested and approved by Kenwood, All models and issues were covered under service warranty. Lots of the information that I recall, I can't find anywhere on the net.

Anyone heard if Kenwood has released a new model??

Guys, a chum of mine recently managed to fry the output stage of his 830s by simply not having a load on the antenna output. Please dont ask as I have absolutely no idea !! Guess he was plain dumb !! The 6146b bottles were totally destroyed too. Now, I have managed to obtain a replacemement choke, (his original was fried to a crisp) which sits between the bottles and have hooked everything up and made a brief attempt at getting something out of this old lady once more. Problem: In all output modes including TUNE, the plate current reading is virtually full scale and even by adjusting the bias on the rear of the rig, it hardly reduces at all. I have checked out the solder joints in and around the pa bottles (which incidently are brand new) and cannot come up with a reasonable theory as to why this should be happening. The 12by7a driver is also new. The HV reading is a little over 900 volts. Clearly something appears to be drawing full plate current and even adjustments on LOAD, PLATE and DRIVE have no impact at all. I have also made an attempt to alter the bias potentiometer for a reduced reading on the back of the rig but this only invites a very minor reduction in current reading. Any thoughts.......Will

Joe, no I have the same old finals that came with the rig. I think all the valves are soft as ALC is a bit erratic and on CW the output power and Ip both drop 10% very quickly before stabilising. But, how would that cause the cathode resistors to fail? If anything, they should be under less stress than for full spec valves. Do the finals arc over? 73 Robin ZL4IG

Robin,

I (didn't know it at the time) had a faulty tube (6146B) that was arcing over as I tuned up, which in turn blew the cathode resistors in my 830s recently (twice!!).
Once I replaced the faulty tube and resistors, it tunes much better now.

Cheers

I received a response from the new INRAD owners today and they said they are not selling back issues and if they had them they would be buried in dusty boxes they havent opened yet. They mentiond that Fox Tango issued a CD rom of their newsletter and perhaps I should check to see if it contained the Kenwood letters as well. I doubt FT group would have included Kenwood letters. So the search continues. If I can find a complete set I will look into what it would cost to make them available to our members. Someone out there has the complete set in a nice binder gathering dust. 73s Terry

Hi Guys,

Here in VK the newsletter came from Kenwood (Sydney) Australia, every three months. It had a lot of Kenwood advertising and lots of specials/discounts for Kenwood User members, but when Kenwood Australia went, so did the club. It covered things along the lines of adding an 8.83Mhz IF output to the TS 530 to enable the SM220 BS8 to be used, adding a meter light to the AT230 via the TS830/530 series. Circuit updates and technical related issues all tried, tested and approved by Kenwood, All models and issues were covered under service warranty. Lots of the information that I recall, I can't find anywhere on the net.

Anyone heard if Kenwood has released a new model??

Subject: Re: [TS-520_820_530_830] Kenwood Users Group Newsletter

Every year I think in the January issue, an index was printed for all the articles of the previous year. There were also supplemental collections of articles for specific rigs that appeared on the market in the 90's. I think I still have a TS-430S collection. If you read Rob's blog at the link I provided, you'll see the history of INRAD. From what I remember without digging them up, there were lots of hinks, mods, tweaks, regurgitation of old problems, kenwood service addenda, etc. Most were submitted by members but, from I remember, generally there was no formal testing to validate the article(s). Over the years, a lot of this same info, has found its way to specific Internet sites that cater to specific

models or model families. I seriously doubt you'll find something there
that hasn't already been covered somewhere on someone's Internet site in
one form or another.

Robin,

I am not an expert on "valves." I just love that term. It has just been my experience that one, or both finals are highly suspect when just the cathode R's pop. Testing RF output valves in a tube(valve) tester does not offer a "real life" test. I have had valves test "good" and in actual use..would not perform...low power...arcing..etc. Mike...w5rkl...and others in this group are way more knowledgeable than I on this matter.

Cheers mate, joe wb7uqu

Robin,

I (didn't know it at the time) had a faulty tube (6146B) that was arcing over as I tuned up, which in turn blew the cathode resistors in my 830s recently (twice!!).
Once I replaced the faulty tube and resistors, it tunes much better now.

Cheers
Chris, ZL1CDP

Hi Friends

Today my TS520SE stopped suddenly with a 'pop'.

When checked, the AC fuse was blown.I opened the covers and noted that one of the small ceramic capacitors across high voltage caps was blown. This is noted as C17 or C18 in the circuit diagram. The high voltage caps are C19 & C20 connected to 800V line in the rectifier unit.

I can replace both after discharging high voltage caps.My worry is why this has happened? Is it due to aging of the caps or for some other reason.Looks like caps are originals but not sure as previous repair notes are not available.
Appreciate any views/suggestions.73's de 4S6RAV (Ravi)

Well the Radio blew the fuse as designed. Replace the caps and check the high voltage to be sure it is correct. If all seems well, forget it and chalk it up to age. I would purchase a spare set to be on the safe side. It's an old radio and I know how much fun they are to use, so have fun and don't try and second guess age. Have fun.Brad KB2CHY

Disc capacitors "typically" do not blow up like that unless their voltage ratings are exceeded.

The manual parts list doesn't show the voltage rating but a 1KV .01ufd cap would not be too much for each cap.

I wouldn't just replace the caps, I would also check the 2 equalizing resistors, R3 and R4, both 470K 1/2 watt. R3 and R4 not only provide a path to bleed the HV filter capacitors to zero volts when power is removed, they also provide a means to equalize the voltage applied across each filter capacitor in the voltage doubling circuit.

The originator of the newsletters, N8RT Rob, is still around. So, in essence, he owned the initial copyright. When he transferred ownership of the business to the first INRAD owner (who is listed on his web site), did he transfer ownership (all rights and privileges) of the newsletter to this owner and/or did this owner transfer the rights to the current owner as part of the overall business transfer? You might pose the question to Rob and/or the first INRAD owner.
It would be wise to get everyone's blessing on what you want to do (preferably in writing), i.e. find the newsletters, scan them, and put them up on the web before you spend the time and effort.

Dear amigos :

I did change the two capacitors for .01 at 2kV units and the equalizing resistors
for a pair of very nice 2 Watt rated 470 k units.
Called a post factory ¨upgrade¨ if you wish...
Also checked the state of the high voltage electrolytic capacitors with an ESR Equivalent Series Resistance meter...
As a result... the two high voltage units were replaced...
The ESR meter is an amazingly useful test instrument !!! You can measure the electrolytics without desoldering them from the circuit !!!
By the way, have a new rare problem with the TS820S... that I will post in another message..

I wouldnt fret over it to much. sounds like sudden escape of the magic smoke, it happens sometimes with age. As said before grab an extra set for the repair just in case.
Do you see any obvious signs of burn or extreme heat, or any evidence it is more then just a part failure? If not, dont worry.

I agree with Mike that these .01 1000v RF bypass disc ceramics do not typically blow up. It would be good to understand why if possible. In addition to changing out the equalizing resistors I would look at C8 and L1 at bottom of your plate choke in the PA cage. It is possible these 2 components have significantly changed value or are damaged and you are getting some RF into your power supply which is not a good thing. While you have the covers off you can physically look at these two components for obvious damage. K4EAA sells a kit for them. Yes--I recently bought an ESR tester and do not know how I got along without one. Best 73s Terry

From: ka9gpx
Topic: 31485 Message: 31506

To all that responded both on & off list,...

Thank you very much for the helpful ideas. Looks like I'll be removing the VCO & Counter module soon,...Hopefully to cure the problem I'm having.

A thought occurred to me that might warrant asking the experts in the group.....As long as I'm going through this "Exercise",...while I have the counter & VCO out of the radio. Is there anything else I should check,...tighten,...do,... internally in the radio chassis before putting the modules back in.

Per all the recommendations all the contacts on the counter module will be cleaned,& screws tightened,...& the VCO will be "rebuilt" per the instructions I found on Gordon's (N6WK) site.... Just curious if there's another "While you've got it apart" type item I should address...

When I can find the time to get to this "Exercise",
I'll post the results...
Thanks again for all the input,

Carl
KA9GPX

Subject: [TS-520_820_530_830] Re: Capacitors blown off!!

Disc capacitors "typically" do not blow up like that unless their voltage ratings are exceeded.

The manual parts list doesn't show the voltage rating but a 1KV .01ufd cap would not be too much for each cap.

I wouldn't just replace the caps, I would also check the 2 equalizing resistors, R3 and R4, both 470K 1/2 watt. R3 and R4 not only provide a path to bleed the HV filter capacitors to zero volts when power is removed, they also provide a means to equalize the voltage applied across each filter capacitor in the voltage doubling circuit.

Topic: 31508 Message: 31509

Glad to see those are available.

The best dust covers I have found for my TS-820S and TS-520 are those zip-up clear plastic cases that bedspreads are packaged in. They are great for storage but a bit awkward for rigs that are in use and hooked up for operation.

Thanks!

Robert

For anyone that is interested... there are a couple of us over on the Kenwood QSO group that will be testing the propagation on 40m tommorrow night at 11:00 EDT (8:00 PDT) at 7.185 +/- 5kc. Anyone who would like to show up on frequency will be welcome. This is not going to be a formal net so there will be no "control operator"; check in, chat, or just see what the propagation is like. I will start calling KA7AYT at about 11:00 EDT. If I fail to hear him, after about 5 min., I will start calling "CQ Kenwood Hybrid Group" or something like that. If there are any issues with T-storms etc. on my end I will post here and on the QSO group page so that everyone will know what is going on. Anyone that can hear me is welcome to call me.

Stan,

There is at least 1 guy on EBAY selling two different colors. The early models had a more grey color..the later...had a slight "olive" tint to the paint. You can go to EBAY and look for "KENWOOD PAINT." I think his EBAY sellers name is "pppmike," and I think he is in the upper middle of the US.

31517. Kenwood Users Group Newsletter

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-05-28 01:03:43 UTC
From: Terry Wagoner
Topic: 31458 Message: 31517

Hi Gang: I am now the proud owner of what I believe to be most of the Kenwood Users Group Newsletters. I have issue No. 11 2/81 thru issue No. 130 12/92. I emailed Rob N8RT the Publisher/Editor regarding copyright issues and await his response. Hopefully I can get permission to scan them and get them loaded on this site or perhaps Gordons site? I will keep you posted. I quickly reviewed a few early issues and saw a tip that I may consider for my TS-830. The fan runs all the time and is only needed in Xmit. The heater switch only uses one set of two contacts. So this tip has you disconnect the fan from the 100v tap on the xfmr and connect it to the heater switch. The fan now comes on when you switch on the filaments. This is an example of kinds of things contained in these newsletters. Terry K9TW

31518. Kenwood Users Net

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-05-28 01:10:49 UTC
From: Terry Wagoner
Topic: 31518 Message: 31518

From the Kenwood Users Newsletters I see that they had a net that met on Sundays around 14.317 @ 2000GMT and would move around 2100GMT to 21.440 (propagation permitting) to better facility west coast and dx stations. The big problem they had was getting people to serve as net control in absence of Rob N8RT and one or two others who occaisionally filled in for him. I read a letter where he appealed for help to keep the net going. Apparently plenty of check ins but few willing to run the net (I have done this couple of times for Midcars on 7.258 and it is not easy).The net was still active in the early 90s as far as I can tell.

My TS-830S has been working great. Easy tune-up to get 120+ Watts out. Problem is tonight the receive went nearly deaf. Very little S-meter movement and only the very loudest of signals are easy copy. I have to crank the AF gain full to hear comfortable audio. This has just happened suddenly...up to tonight the receive on the rig has been very responsive. I hope this is an easy problem to get straight. Any suggestions very much appreciated.

Joe: How is your marker signal (xtal calibrator)? Do you get about S9 signal with it on and vfo tuned to 25khz interval? Common failure is Antenna Input Coil L41 on the RF Board. As far as I know they are no longer available and have to be rewound. They use very small guage wire. Ken K4EAA describes rewind procedure on his website. Terry K9TW

Joe--just to make sure on same page. When describing signal strength there is difference between "loud" and "strong". I am trying to undertand if you have an RF amp or AF amp problem. With low strength and loud volume Calibrator signal it sounds like RF problem in front end. So, if you turn the RF gain up full clockwise and make sure RF Attenuator button is Off and have AF gain turned up clockwise to comfortable listening level, you tune across band and hear no or just very weak signals with very little S-meter deflection. Is that correct? Is that on 40 as well as 20 or 15 meters?

Also, have you checked your coax connector to the so-239 chassis connector on back of rig and any jumpers you may have connecting wattmeters, antenna switches etc. You could have a loose antenna connection. Check simple stuff first.

Do you have a signal generator? Can inject test signal to see where you are losing the signal ie at RL-1 antenna relay, at L41 antenna input coil, and at Q1 rf amp mosfet. Do you have RF millivolt meter or VTVM w/rf probe? There are level diagrams and couple of test points on the RF board to measure receive level. Do you have service manual? Terry K9TW

Terry,

We are going to try again this Sunday at 1:00 PM EDT (17:00 UTC) on 21.285 and would be thrilled to hear you there. We made the 40m sked so late in order to give Chris over in Greece a chance to see if he could hear us over here in the U.S. Anyway, I think he will have a better chance on 15m Sunday. I am going to have to get busy and get a wire up for 20m.... I think 20m is going to be the "key" to getting a Kenwood group together on the air.

Topic: 31525 Message: 31525

Hi Gang--For those of us experiencing 6146 final tube arc overs and blown cathode resistors in our TS-830s here is an exact quote from International Kenwood Users Group Newsletter February 1981 review of the New TS-830S....." A note within the owners manual states: During transmit you may occasionally hear a small popping sound or High Voltage arcing sound, this will be the 6146B power tubes and is considered normal". Additionally the review goes on to say ...Final plate and load tuning should be accomplished within 10 seconds. If more time is required return to receive for more than 20 seconds. Note: The TS-830S under test did arc a few times."

I find this to be amazing coming from 1981 review of new TS-830S with new tubes. I wonder if this was with the S2001 or S2001A tubes?

Had I been performing this test and review on a newly issued TS-830s in 1981 I think a phone call to Japan would have been in order. If we are to believe this review, arcing 6146 tubes in a Kenwood TS-830 was considered normal from the factory and noted in the owners manual. I guess I would have to see an early manual to believe this.

Thought you might be interested in this. Have nice holiday Terry K9TW

Dan,

This morning I heard nets on both 7190 and 7185. I checked between 7175 and 7200 for an hour but didn't hear you. There was rag chew on 7182 that I tried to break in to. They could tell I was there but couldn't copy. Conditions weren't good. I had heavy rain and thunder and from listening to the net Florida was the same. The band was very noisy here. Noise was S5 - S6. I listened on 20m and it wasn't open at all. Perhaps my evening, your morning could be better. I may check conditions at dusk tonight but were having a barby so ..... maybe not.

Hi Terry,

I "think" the statement referring to "popping" sound actually meant a "clink" sound which can occur in a vacuum tube such as the S2001/6146A or S2001A/6146B tubes during tune up. The "clink" sound is a very high pitched low level sound that is heard when the elements in the tubes warm/heat up. It doesn't happen all the time. I've heard this quite often, not only in Kenwood hybrids but in other transmitters with 6146 or other final tubes. I hear it every now and then in my AL-811. It doesn't mean there's a problem, it simply means the elements in the tube are heating up and vibrating resulting in the "clink" sound.

There are various "misleading" statements in the manuals that can confuse the operators and I based these on translation issue from Japanese to English. I guess there is no such word such as "clink", translating to English, other than "pop" to explain the sound coming from the final amplifier. I do not believe the statement is referring to the cathode resistors failing but more about what I indicated above.

Terry...

Thanks for the info on the newsletters. Very interesting stuff! I for one sure hope that you get to make these available to the group. Seem as though you can't always believe everything you read, but still very interesting all the same.

The Marker (Calibrator) signal flows directly from the PLL Unit plug 4 pin 2 "MKR" to the RF Unit plug 4 pin 2 "MKR". The Marker signal does not flow through the RF ATTN push button switch nor does it flow through the antenna T/R relay. The position of the RF ATTN switch has no affect on the Marker signal level.

If the Marker signal is weak on all bands then it is quite possible that Terry is right, L41 is bad.

You can inject a HF signal on both sides of L41. First inject the signal to the primary windings of L41 at TP1 on the RF Unit. Keep the signal level less than 1uv ("uv" stands for "micro-volt"). If the signal is very weak, inject the same signal on the secondary windings at the junction of L41 and C42. You may have to increase the signal level a bit. If the receive generator signal indicates a significant increase, i.e., the S meter rises to S9 or so, then most likely L41 is bad.

Again, the signal generator's output signal level must be kept low to prevent the RF amplifier from being over driven. If your signal generator has a built in audio generator, most typically do, turn it ON then apply the signal at the points above. You should hear the beat note AND the generator's audio signal in the speaker. The beat note AND audio signal can results in a 2 tone sound coming from the speaker. If you hear this, turn the generator's audio generator output "OFF" then adjust the VFO for a zero beat. Zero beat mean there the VFO is adjust to the point where you no longer hear the beat note. At this point, turn the generator's audio output "ON" and you should hear the generator's audio signal in the speaker.

Last night, I tried to catch the informal Kenwood Hybrid net, but only caught the late 40m OMISS net. Since I was already tuned up, I attempted to check in. That was my very first HF transmission ever.

It turns out that the things I have learned with your help on this forum is indeed enough for a hack like me to get a tech special TS-820s back on the air good enough to talk to folks from Delaware to California!

The patience of the OMISS net in working with new users like myself is certainly appreciated. I think I logged 14 contacts in my first experience. Everyone kept giving me a chance to "get it right." *laughs*

What antenna was I using? Oh a 40m dipole strung up on a suburban fence no more than 6 feet off the ground. I'm sure a better antenna situation would go a very long way to improve things as will continued efforts to find and correct the multitude of problems with my classic TS-820s.

Certainly here in the age of the internet, talking to folks 1,000s of miles away is as easy as picking up a mobile phone, but now I understand the magic that hams felt before VOIP and unlimited minutes were commonplace. I also sheepishly look back at the excitement I experienced talking 70 miles on a modern, turnkey 2 meter mobile rig as small potatoes compared to talking 1,700+ miles with my classic Kenwood.

I am really looking forward to talking to other Kenwood hybrid owners on HF now. I have no idea what my radio sounds like on the air. I need feedback to help me figure out what other adjustments are out of whack on my gear. I need help figuring out where in the world my mic gain needs to be, whether or not my compression is set correctly (or if it even works!) and things like that.

Thanks again team. You helped keep another classic Kenwood radio doing what it was designed to do. Hope to catch y'all on the air soon!

I'll try to catch this Sunday 1700UTC. I don't think my longwire makes a very good 15m antenna, but I'll try none-the-less.

I tuned in on 7.185 last night and caught the OMISS late net. I'll post up about that in a separate thread.

Greetings group.

I agree with Mike's statement about the "clink" sound. I have heard the "popping"....followed by the "smell of smoke" and ZERO Ip, numerous times due to faulty final tubes causing the cathode R's to go. I have also heard the "clink" sound...NOT followed by the "popping" and no smell of smoke while "tuning up." When any object gets warm/hot...it will expand...as will the tube internals and the glass envelope. For what it's worth.....

To all the Veterans: THANK YOU

Hi Terry,

I "think" the statement referring to "popping" sound actually meant a "clink" sound which can occur in a vacuum tube such as the S2001/6146A or S2001A/6146B tubes during tune up. The "clink" sound is a very high pitched low level sound that is heard when the elements in the tubes warm/heat up. It doesn't happen all the time. I've heard this quite often, not only in Kenwood hybrids but in other transmitters with 6146 or other final tubes. I hear it every now and then in my AL-811. It doesn't mean there's a problem, it simply means the elements in the tube are heating up and vibrating resulting in the "clink" sound.

There are various "misleading" statements in the manuals that can confuse the operators and I based these on translation issue from Japanese to English. I guess there is no such word such as "clink", translating to English, other than "pop" to explain the sound coming from the final amplifier. I do not believe the statement is referring to the cathode resistors failing but more about what I indicated above.

Mike--that may explain it as they never made any mention of cathode resistors, but the reviewer doing the testing of the new rig said the rig "arced" several times during the testing.That doesnt sound like translation problem? I would hope an experienced ham testing a new rig would know what a "arcing" sound was. Maybe not. Yes I have heard the "tink or clink" of a glass tube warming up and cooling down. Very different sound from a pop or high voltage arcing. Also, very strange to actually write this in the owners manual. I still would like to see the exact texts. Terry

Steve--My son in law is a VOIP generation person and he cant understand the magic of ham radio. I remind him that he needs connecting wire and/or fiber optic cable to complete his call around the world. It is still very amazing what 100 watts (light bulb power) and a wire 6 foot off the ground can do as you found last nite. Get that dipole higher and you should do better. The magic never goes away! Terry

31535. TS-820S no meter reading in TUN position

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-05-28 17:13:31 UTC
From: jim.goldring
Topic: 31535 Message: 31535

I recently acquired a really nice TS-820S from an estate sale. It's been off air for probably at least 2 years (SK died about 2 years ago or more). In going through the tune-up spelled out in the manual, I can't get a meter reading plate current (Ip) after peaking the ALC reading with the drive control, mode switch in TUN. When I come back to dip the final with meter reading Ip and mode still in TUN, there's no plate current induication, even when CAR is increased. But putting it in CW mode I can dip the plate normally, and the rig seems to work just fine. So far all I've done to this rig is to remove the VFO, lubricate its front bearing and use DeOxit on its rear bearing. I'm about to reassemble it but still am puzzled about the above symptom. Is this a problem, or am I just missing something? THANKS!

73,
Jim, AK7R

Terry,

Yes, arcing is entirely different.

Arcing can occur when a tube's voltage limits are exceeded. This type of arcing is not only heard but seen. The sound and visual is quite different than other types of arcing. A tube can arc but you may not see it, typical with receiving tubes. I experienced that with an HW-101. The arcing tube, the receiver's RF amplifier, arced intermittently, produced a 40 over 9 S meter indication even when the antenna was removed. Removing the tube and replacing it with a known good tube eliminated the problem.

Hi Jim,

Look on the rear of the 820, there's a slide switch labeled "SG". Make sure it's in the "ON" position. If it's in the "OFF" position, there will be zero IP current indication in any mode.

Terry, Mark: Thanks for the replies. I'm going to get into it this afternoon and see what's up...thanks for the tips on what to look for.

Connected directly to a G5RV with RF gain and AF gain turned up full, I'm hearing no signals on any band...only noise. I can hear the marker audio in the speaker fairly loud, but the S-meter readings are way down. The S-meter readings with the calibrator on vary from band to band: 1.5 Mhz = S3, 3.5 Mhz = S6, 7 Mhz = S2, 14 Mhz = S1, 21 Mhz = S0.

I have the Service manual and some basic tools, hopefully with your guidance I can locate the problem.

Mike:

Note that Jim says that everything is FB in CW mode and he can dip the plate. I assume that means he has some plate current in CW Mode but not in Tune mode. And he can peak the ALC as well.

I guess that eliminates the SG Switch, the relay, the driver tube, and the finals as problems, as well as the usual burned out resistors.

Can't figure out what this problem could be other than a Mode Switch Problem, as unlikely as that sounds. Could he have messed up something when he pulled the VFO to clean it? I pulled the VFO in my 820S and nothing comes to mind. What do you think?

I suppose cleaning the Mode Switch would be a good idea. In fact, clean all the switches, given that the set has been sitting for a long time

Joe--OK sounds like your AF is working fine and it is a failed L41 antenna transformer. Hopefully didnt take out Q1. You didnt inadvertently get some xmit RF into the so-239 on back of rig did you? Will be a little hard to trouble shoot if you dont have signal generator or a noise bridge to inject a signal after Q1. I wonder if you could connect a mini-clip test lead to Test Point TP-4 on RF Board and touch it with your hand or touch to center pin of your antenna coax lead and see if RF sigs come way up? I will let Mike W5RKL run with this one. I have never replaced a failed L41. By the way if you dont have a Rf sig generator, Elekraft makes a nice little sig generator in their Mini Module series. For around $70.00 you get a very accurate 1uv and 50uv signal source. Great for testing receivers and aligning S-meters. Good luck. Terry K9TW

As the only antenna that I can cram into my small backyard, it works great. On 80 through 10. It isn't a beam antenna, but I can and do operate contests with it all the time. To get it to work, you need to have a tuner (AT-200) and be at least 1/4 wave up. (60 ft in my case). I use it with my TS-830, TS480HX and my Drake 4 line.

Please don't high-jack the thread with a discussion of antenna's. The subject of the thread is about a low receive issue inside the TS-830S. While antenna discussions can be interesting... it's not going to help much with my original question. Thanks.

Continuing with the subject of the thread: After opening the case, I can see getting at the RF board to make tests or repairs is going to take quite a bit of disassembly. Any suggestions for a newbie on the best way to get at that board without messing it up. Frankly, I'm used to working on Drake Twins or my FT-101B, where getting at the components is quite a bit easier to say the least. Thanks in advance.

Joe--If you have the top cover off your rig here is simple test for Q1 RF amp. This assumes you do not have a signal generator.

Set your rig for 40 mtrs, turn RF gain to max, peak the drive with the xtal calibrator on and then turn it off.

On right side of rig is the RF board. You will see 3 chain driven air variable capacitors. VC-1 is the first one. You will see 2 solder lugs standing upright on top right hand side of VC-1. There is nothing landed on these lugs. Touch either one of these lugs with your finger or a test lead and you should get a large increase in signal.

This proves that Q1 RF Amp is working. If you get no increase in signal then locate TP-4 a square upright post close to Connector 10. Touch there with screwdriver with clip lead on it. Be careful not to slip off. You should get increase in noise but not as dramatic proving that Q2 Buffer Amp is working.

I could copy signals on 40 meters with just 18 inch clip lead touched to either of one these two points. I guess my money is still on L41 being shorted. If either L41 or Q1 are bad you will need to remove the RF board to replace them. Hope this helps. Terry

Joe-Unfortunately you are correct the RF board is the hardest board to remove and reinstall. Sure helps if you have done it before. I guess it depends on your confidence level. It may be worth seeing if Gordon has the time to repair it? I think you should troubleshoot to determine if there is failed component on the board first and then see if you want someone to talk your thru the removal and install. That probably should be done off list. Terry

Please re-read my original post. If you are *not* using an antenna tuner with your rig with a G5, you'll get what you are describing. Low signals. Been there done that. Beats tearing into your rig. Jim

Please don't high-jack the thread with a discussion of antenna's. The
subject of the thread is about a low receive issue inside the TS-830S. While
antenna discussions can be interesting... it's not going to help much with
my original question. Thanks.

Continuing with the subject of the thread: After opening the case, I can see
getting at the RF board to make tests or repairs is going to take quite a
bit of disassembly. Any suggestions for a newbie on the best way to get at
that board without messing it up. Frankly, I'm used to working on Drake
Twins or my FT-101B, where getting at the components is quite a bit easier
to say the least. Thanks in advance.

Thanks for the replies. This symptom happened before I removed the VFO for cleaning/lubricating. The screen voltage switch is ON and everytghing seems OK except for getting no Ip indication in TUN mode. I'll continue to work on this when I get it all put back together.

I find L41 shorted quite often. I have found them burnt to a crisp to
some that just slightly overheated.

Well I'll be, you're right Robert. It appears I missed the section where CW mode works fine. I'll have to give it some more thought and respond in a little while.

Thanks for pointing out my mistake Robert. I should have seen that.

Terry here's what I get with your suggestions:

Set your rig for 40 mtrs, turn RF gain to max, peak the drive with the xtal calibrator on and then turn it off.

On right side of rig is the RF board. You will see 3 chain driven air variable capacitors. VC-1 is the first one. You will see 2 solder lugs standing upright on top right hand side of VC-1. There is nothing landed on these lugs. Touch either one of these lugs with your finger or a test lead and you should get a large increase in signal. *Touching VC-1 lugs increases the signal slightly, not much. Touching VC-2 lugs greatly increases the signal.*

This proves that Q1 RF Amp is working. If you get no increase in signal then locate TP-4 a square upright post close to Connector 10. Touch there with screwdriver with clip lead on it. Be careful not to slip off. You should get increase in noise but not as dramatic proving that Q2 Buffer Amp is working. *Touching TP-4 greatly increases the signal.*

I could copy signals on 40 meters with just 18 inch clip lead touched to either of one these two points. *I can copy some sigs with a test lead connected to VC-2 or TP-4*. I guess my money is still on L41 being shorted. If either L41 or Q1 are bad you will need to remove the RF board to replace them. Hope this helps. Terry

Thanks,
Joe

Jim: Thanks for your comment. I didn't explain in my original post that I tried other antenna's both thru the match and direct with no difference it signal strength. I thought it unnecessary to cloud the issue with extraneous data. When my TS-830S was working, it picks up signals even connected to a dummy load!! Now it's deaf, through a tuner or not.
Regards,
Joe

Joe--VC-2 and TP-4 are essentially the same place. You are coupling a signal to the base of Q2 the buffer amp and proving it and the downstream mixer are working to produce your receive IF signal. The gate of Q1 is probably being shorted by the shorted L41 transformer. Difficult to tell without taking voltage readings at Q1 which is nearly impossible from top side of board. I think it is time to think about board removal to rewind L41. Lets see what Mike thinks. I dont know if Bob Mansker has any spare RF boards or not? Terry

Joe--one more thing if you take the board out to replace L41 be sure to test Q1 and diode D2. If in doubt replace them. There are subs available for the mosfet. Terry

31556. Re: TS-820S no meter reading in TUN position

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-05-28 23:04:07 UTC
From: roberteleazer@rocketmail.com
Topic: 31535 Message: 31556

Well, here is a thought or two.

With my TS-820S I had a problem with being unable to get low enough idling current in SSB mode. I could not get down to 60 ma. You told me that was wrong and I concluded that it was the carrier supression not being adjustd correctly. I adjusted that and that fixed pit.

When that condition existed I also had a problem with the finals being "over-neutalized." During the neutalization procedure I could adjust the capacitor so there was no oscillation in the output. Mimimum voltage on neutralization equated to no output. When I got the carrier suppression adjusted then minimum voltage on neutralization was in fact a minimum as viewed on the Oscope. There was still RF output in Tune Mode when so adjusted.

So, is it possible that the carrier supression is misadjusted and that someone has adjusted the neutalization so that there is no output and no Ip with the voltage turned down as it is during Tune mode?

Regards,

Robert

Jim,

I had the same issue with my 830s. No IP in tune mode. I found that the voltage divider resistors on the rectifier board were bad. R15 and R16 (56K). One was completely open and the other was very high. I used to peak the alc in tune and then have to switch to cw and dip etc. Now tuning is as it should be. I don't know if the 820 is the same circuit - but I would think that it would have something similar...just a thought.

Hello Jim,

You say the 820, in TUNE mode does not show any IP current. Do you get the same loss of IP current in both USB and LSB as well?

I bought a Workman DM-507-4 hand mic for my TS-830S, had to completely rewire it of course but works fine. You can find them for $15 on ebay.. found that out after buying mine for $25 at the CB shop at the truck stop south of the city..

I have an old ELECTROPHONE CB mic on my TS 520S, and find it works well and I only had to re wire the plug to suit the TS520S.

I bought a Workman DM-507-4 hand mic for my TS-830S, had to completely rewire it of course but works fine. You can find them for $15 on ebay.. found that out after buying mine for $25 at the CB shop at the truck stop south of the city..

Topic: 31565 Message: 31565

Hi everyone, my TS830s has a narrow 250hz CW filter installed.
Question: When I switch between CW Wide to CW Narrow, there is a considerable reduction in AF !! Certainly the filter does its job and isolates the CW I am trying to capture but the received audio overall seems to drop away. I also have to adjust my IF shift counter clockwise by approximately a quarter turn to bring the signal in to what I am assuming is the centre of the filter pass band. If I leave the IF shift in its 12 oclock position, I cannot hear the signal in the narrow filter position. Any thoughts ? Will

Hi Will--If you leave the IF shift at 1200 can you carefully re-tune VFO or RIT and get signal in? It sounds like you also have the YC-455C cw filter installed as well? I experience some insertion loss in CW-N position. I have the YK-88C and the YG-455C installed and it allows me to use the VBT to narrow the passband for CW work that I do. I think Kenwood recommends using the CW filter combination that is the widest and then use the VBT to give you needed flexibility. Maybe one of the serious high speed CW operators on here will have better idea if your condition is normal. The owners manual (pg 24) states that you can have a combination that results in the passband being narrow on one side. You need a frequency counter to measure the IF Shift at TP3 on the IF board (+/- 1.1 khz). It is possible that you have Trimmers TC2 and TC3 set too thin, These are user adjustments accessed thru the bottom of the rig. The Survivors guide Section 8.4 details a procedure using the Xtal Calibrator to align the USB/LSB Carrier Oscillator, Also, Ken K4EAA describes how to do it on his website under the FAQs and Tech Question sections. He does it by ear and Survivors guide does it using S-meter. You can adjust the trimmers to shift passband lower.

Will--If the covers are on I think I would start by adjusting TC2 and TC3 accessed thru bottom holes to shift the passband down a little. If you dont have copy of Survivors Guide it is readily available on line. The TC2 and TC3 adjustments are kind of user preference. I check mine occasionally as they tend to drift. An insulated tuning stick with small thin metal tip is needed as these are ceramic trimmer caps. Terry

A few of us are going to try 15m today at 17:00 UTC (1:00 PM EDT) on 21.285 +/- a few kc. Anyone that would like to join in are welcome. This will be an informal gathering and there will be no control operator. I'll try calling CQ a few times... if you can't hear me try calling CQ your self and see what happens. Perhaps we can get something going on the air today... who knows.

Dan KI4AX

The IF Shift control "varies" the "Carrier Oscillator" frequency, 8831.5Khz (USB and CW) or 8828.5Khz (LSB), that is applied to the PLL Unit (see the 830's service manual page 4 for details).

By varying the Carrier Oscillator frequencies you also cause a variation in the PLL Unit's "VCO" (Voltage Control Oscillator) frequency that is applied to the RF Unit.

The PLL Unit's "VCO" signal is applied to the RF Unit where it is mixed with the incoming signal frequency to produce the 8.830Mhz "RIF" signal. The RIF signal is then applied to the IF Unit where it is then applied to the first crystal filter (8.830Mhz center frequency).

Placement of the 8Mhz "RIF" IF signal in the filter's bandpass varies the filter's ability to reduce/eliminate adjacent frequency interference. Depending on which direction the IF shift control is rotated determines where in the crystal filter's bandpass the 8Mhz RIF signal will be placed.

If you rotate the IF shift completely CW or CCW you will notice in one direction the audio will become high pitched while rotating in the opposite direction the audio becomes muffled or low pitched. That an "audio" way of hearing the 8Mhz IF signal being moved from one side of the crystal filter's bandpass to the other. If you tune in the Marker signal with the IF shift control centered and a beat note is heard, adjust the IF shift throughout it's travel, CW and/or CCW. You will notice at one point during the rotation the beat note will or almost disappear yet in the opposite direction you will hear the beat note much more clear. Try this while receiving an incoming signal and you will see/hear that you can "tune out" or "significantly reduce" other signals so you hear only the Marker beat note.

If the Carrier Oscillators are misaligned and the IF Shift control is centered, the 8Mhz RIF signal will fall in the wrong place in the crystal filter. I recommend checking the Carrier Oscillator alignment to ensure it's correct with the IF Shift control centered. Again, see the 830 service manual's alignment steps for details on performing the checks and, if necessary, any adjustments to the Carrier Oscillator.

I listened in Denver, CO, and called CQ a couple of times. Nothing heard.
I can hear CA and OR running over CW mode at the bottom of the band.
Want to try again at 1730UTC, Gordon?

I listened (chicagoland area) heard nothing. Called CQ, heard nothing.

Band (15m) not in good shape today. I did hear something now that I
think about it -

lightning crashes!

I listened from Florida, put out some calls on 21.285 but only heard a faint QSO going on 21.275. Sound like the station I could almost hear was one of them ferriners, and they have been about the only people I have talked to on 15M in the past.

Okay, so where do we try next? The TS-520 loaded up superbly on 21.285, using my new MFJ-969, 100W CW out with an SWR of 1.5.

It was about the same for me as it was for everyone else. I called CQ and did hear W1WIU down in the static. We just barely had a qso. Again, I think 20 meters is the place to try this... at least until the bands open up a bit more. However, I can not try it right now because I need to get an antenna up for 20m.

31583. Another TS-820 display issue

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-05-29 23:47:30 UTC
From: kb0asq
Topic: 31583 Message: 31583

Hi all,

I have a TS-820 and a TS-820S that I am getting ready to sell and I want to get some of the bugs out before I put them up for sale.

Starting with the TS-820, it has the optional display unit. I had it recapped about 18 months ago, and it has been setting pretty much unused since then.

On all bands, after it sits for about 15 minutes the Display will start to move up and down on the last 2 digits of the display. If I move the band selection back an forth rapidly a few times it will quit. This behavior is exhibited on all bands.

I have taken the display unit out and cleaned all the contacts with Deoxit D100 and also the band wafers. I have checked the 9 and 3.3 volt power source and they are all well within specs and do not move more than .05 volts when left on.

Do I just need to clean the band switches some more? Is this just the usual operation of the Display unit?

I let a friend try the TS-820S that I got at a local auction last fall and he says it exhibits the same behavior. I haven't had the case off of it yet.

Terry:
Taking the RF board out was less of a problem than I anticipated. It took about 45 minutes and I had the board free. I located L4 and removed it from the board. My initial readings were no short between the primary and secondary -- and I had continuity on the windings themselves. Later on I retook readings and this time there was no continuity on the windings??? Very strange. So, I proceeded to disassemble L4 and have a look and the whole thing came apart in my hands. I'm not sure I'll have success in trying to rebuild it. Seems like you'd need to be a brain surgeon to do it right. If I can figure out how to post a few photos I will. I'm out of ideas and kind of brain dead for this evening.

From: Terry Wagoner
Topic: 31519 Message: 31590

Joe--All is not lost. L4 is not a transformer. It is a simple tuned core coil...an inductor. It is shunted by C7 1200pf cap. Together they form a parallel resonant circuit that offers Hi-Z to 8.83 mhz. In short, it blocks the 8.83 Mhz IF from getting into RF amp. So, in a pinch you could install a miniature axial lead RF choke in its place. It would be better to have a slug tuned coil form so you could adjust it to resonance at 8.83mhz, but after rewinding L41 you could get your rig back on the air with installation of a choke coil at L4. There are a couple of other series resonant traps in this string including one at L4/C7 junction that you can tune later to address any 8.83.

I did the math and you need a .270 uh coil. There are a lot of combinations to get this ie 10 turns of No. 32 magnet wire on a 1/8 inch core. Of course it would be best if you had LC bridge to adjust coil. If you are not up to winding a new L4 I would try the fixed RF choke approach.

The good news is that .270 uh is a standard value rf choke. Mouser and Digi Key sell them for literally pennies. I took a brief look and Surplus of Nebraska has some miniature IF cans and slug tuned coils and they have one that would tune in the range you need and is thru hole mount. So in absence of a replacement L4 or a replacement RF board, I would install a miniature .270uh axial lead choke and get rig back on the air. Best I can do for you. Keep smiling. Terry K9TW

Terry:
That's real good information. N6WK has kindly offered me a replacement L4...
which would be great given my experience level. I will next move on to L41
and check it's condition, rewinding it as needed -- hoping to keep self
inflicted damage to a minimum. :?)
Thanks,
Joe

Joe--That is great! Maybe before he ships it he can bridge it and see if my calc @ .270 uh was close. Well--as you found out you will need a steady hand and magnifier head set. L41 is very fine wire and not sure my old eyes and hands would be up to the task. As you noted "brain surgery". 73s Terry

Hi Terry,
I measured the coil L4 and it measures out at .290uh
Joe, I have the coil in the padded envelope and will ship it tomorrow to you.
I don't have any spare L41 coils to send though LOL
Any other small parts you need before I seal the envelope?

73,
Gordon

Topic: 31583 Message: 31595

Reportedly, according to an article over at Mods.DK, the electrolytic capacitors in the carrier unit can cause this. They recommend replacing them and using a larger cap for the 9V input to the lower carrier board.

On the other hand, the Kenwood TS-820 service bulletin says that noise can be caused by a bad tantalum cap on the PD board in the VCO/PD module. I thought I had noise and so I replaced the tantalum cap with a ceramic bead cap of the same value. And then I found I had the type of instability you describe. I replaced the assembly with a spare and have not investigated why the other module develoepd that problem. But - it appears that the caps on the PD board can cause this too.

Good luck!

Thanks Gordon-- Close enough considering I used all my fingers and toes! I suspect tuning the slug would have seen .270uh somewhere in the range. Kind of has to inorder to resonate at 8.83 mhz with 1200 pf cap. Maybe Bob Mansker has a L41? I suspect he has spare RF board but not individual components off the boards? If I ever get a spare RF board I think I will guard it like gold! 73s Terry

I bought a TS-530SP just before I got my General. I cannot tell you how many times I have heard people say that it was the best radio ever and that they are sorry they ever sold it. On this basis, I have vowed never to let mine out of my sight. Why do the rest of you sell yours and then say how much you miss it and how sorry you are to have sold it?

I’m glad I have been able to learn from the experience of others and I recommend it highly. ;-)

Rick KF7JFU

2 million series, wow, that is an early Silver version.
I have a cure for the loose connector problems on the IF board.
When I get those that are really loose, What I do is unsolder them,
one at a time, and epoxy the connector to the board. Then I go back and
solder all the terminals again. Makes for a nice mechanical connection
and a great electrical connection. Once you do that, no more wiggly
connectors and when you plug in the connecting cables, all stays secure.
One of the errors guys make is trying to unsolder from these boards
using too little heat. Therefore the iron has to stay on too long and
sometimes lifts the trace.
I use more heat and get in and out fast.
Yes, I hate it when I buy a rig that has some guys call, soc number or
license number engraved into it.

Gordon: Thanks very much for sending the L4... I am in the process of checking out L41 ? when I pulled the cover off I noticed a clean break in one of the wires. I think I'll have to rewind the coil. Right now I'm trying to figure out which side is the primary and which side is the secondary. For the life of me I can't find the darn thing on the schematic to double check which end is which -- must be blind. I'm also wondering how important it is use exactly #42 enameled wire? I have some old RF chokes I can get wire from if the size isn't super critical.

No other parts needed!! Thank you.

Topic: 31519 Message: 31602

Because we upgrade to TS-830s (in my case 2 of them) and we cannot justify having that many rigs. Besides I promised my wife I would sell one after testing sensitivity and selectivity. I think they were equal in sensitivity but the VBT and full filters in the 830s win out on selectivity. Just anecdotal no measurements. I am of course my own man and my wife cant tell me what to do! Hang on to your 530SP as long as you can. Terry

I bought a TS-530SP just before I got my General. I cannot tell you how many times I have heard people say that it was the best radio ever and that they are sorry they ever sold it. On this basis, I have vowed never to let mine out of my sight. Why do the rest of you sell yours and then say how much you miss it and how sorry you are to have sold it?

I'm glad I have been able to learn from the experience of others and I recommend it highly. ;-)

Yes-- I had a guy call me the other evening asking me if I had a spare RF board.

I directed him to Bob. Surprised he hadnt heard of him. I do have another TS-830

I bought down in Florida this winter and brought back. It is a 2 million series and a little rough cosmetically and you know about the connector problems I had on the IF board. I do not plan to part it out. Right now it is working well. It is nice to be able to take comparison measurements etc. Someone took a chisel and carved their soc number on rear panel. I bought a replacement panel off fellow in Florida and havent got around yet to replacing it. I did sell my beautiful TS-530SP and already miss it! 73s Terry

Hi Terry,
Yes, I am sure the slug would allow it to move down to .270 uh.
I didn't run the slug in or out to check. I just checked it as it was when I removed it.
I have TWO RF boards for the 830.
One is good and complete, the other is one I rob parts from such as this L4 that Joe needs.
Last time I spoke with bob, he was out of RF boards.

73,
Gordon

Yes-- I got my IF board connectors (3 of them) repaired using your method and
you have converted me to the high heat and get out quick camp. Thanks

movement

2 million series, wow, that is an early Silver version.
I have a cure for the loose connector problems on the IF board.
When I get those that are really loose, What I do is unsolder them,
one at a time, and epoxy the connector to the board. Then I go back and
solder all the terminals again. Makes for a nice mechanical connection
and a great electrical connection. Once you do that, no more wiggly
connectors and when you plug in the connecting cables, all stays secure.
One of the errors guys make is trying to unsolder from these boards
using too little heat. Therefore the iron has to stay on too long and
sometimes lifts the trace.
I use more heat and get in and out fast.
Yes, I hate it when I buy a rig that has some guys call, soc number or
license number engraved into it.

Terry,
Be sure to tell your wife that! Hi Hi
She who must be obeyed, might have a different answer LOL

73,
Gordon

Because we upgrade to TS-830s (in my case 2 of them) and we cannot justify
having that many rigs. Besides I promised my wife I would sell one after testing
sensitivity and selectivity. I think they were equal in sensitivity but the VBT
and full filters in the 830s win out on selectivity. Just anecdotal no
measurements. I am of course my own man and my wife cant tell me what to do!
Hang on to your 530SP as long as you can. Terry

I bought a TS-530SP just before I got my General. I cannot tell you how many
times I have heard people say that it was the best radio ever and that they are
sorry they ever sold it. On this basis, I have vowed never to let mine out of
my sight. Why do the rest of you sell yours and then say how much you miss it
and how sorry you are to have sold it?

I’m glad I have been able to learn from the experience of others and I recommend
it highly. ;-)

Rick KF7JFU

Yes-- I had a guy call me the other evening asking me if I had a spare RF board.

I directed him to Bob. Surprised he hadnt heard of him. I do have another TS-830

I bought down in Florida this winter and brought back. It is a 2 million series and a little rough cosmetically and you know about the connector problems I had on the IF board. I do not plan to part it out. Right now it is working well. It is nice to be able to take comparison measurements etc. Someone took a chisel and carved their soc number on rear panel. I bought a replacement panel off fellow in Florida and havent got around yet to replacing it. I did sell my beautiful TS-530SP and already miss it! 73s Terry

Hi Terry,
Yes, I am sure the slug would allow it to move down to .270 uh.
I didn't run the slug in or out to check. I just checked it as it was
when I removed it.
I have TWO RF boards for the 830.
One is good and complete, the other is one I rob parts from such as this
L4 that Joe needs.
Last time I spoke with bob, he was out of RF boards.

73,
Gordon

Is anyone going to be on today? I just got back from camping and was wondering? I have not had time to listen to see what is open yet, but will be around the radio the remainder of the day!

Hi Joe--Did you get an answer to location of L41? If not, on schematic look on right side for the RF Unit bounded by dashed line. Find Connector 3 on left side of RF unit. Find ANT terminal and follow Bold Black line from ANT down to L41. You will see Primary on left side and Secondary on right side. So the Xfmr is a Step UP. The Primary has 6 turns and the Secondary has 26 turns (per K4EAA FAQs). If you have the Service Manual look at X-ray view of RF board on Page 12. Look down at L41. You can see on Left Side it has 2 Pins and Right Side has 3 Pins. The center pin on Right Side is Not Connected (NC). The Secondary winding is connected to the Top 2 pins. The Top Left goes to C42 and the Top Right goes to L12. The Primary Winding is connected to the Bottom 2 pins. The Bottom Left goes to ground and the Bottom Right goes to junction of C7/L4. As I mentioned to you I have never wound an L41. Per Kens K4EAA web site he says to try to solenoid wind and not scramble wind. When you unwind the wire you will be able to tell which winding was wound on the bobbin first. I guess if I were doing it I would wind secondary first and then put primary over it, but it shouldnt really matter. Gordon will have some tips for you as he has wound new L41 xfmrs. Good Luck Terry

Terry:
Thanks... found it!! What do you think about the wire gauge? Do you think that would be critical? Even with enlarging goggles on, that is a mighty small piece to work with -- That wire is like a human hair width. I wonder why the designer's used such a small gauge in the input circuit if not for it to also serve as fuse to protect the front end.

Joe--I dont think they had fusing in mind. At that stage of the receiver you are dealing with micro-volt signals so current will be miniscule so you dont need heavy gage wire. Yes--that wire will be very hard to see and very easy to break if too much tension during winding.That is why I suggested you ask Gordon about any lessons learned.

If you increase the wire gage it will have an effect on the inductance of the winding for same number of turns. If you change the inductance you will change the impedance ratio of the Xfmr. I dont think it would be real critical. The Xfmr turns ratio is about 4.34 to 1. That is the more important characteristic to maintain. Changing wire guage wont effect the turns ratio unless you cant get same number of turns.

So long winded answer is I would try to wind it with 46 guage and if you cant then consider going up in guage as long as you can still get 26 turns wound on the bobbin.

I have looked for miniature and sub-miniature RF xfmrs (via Google) and I find several that come close in value but not sure about correct dimensions for PC board thru hole mounting. It looks like a wide band 4:1 xfmr would work just fine. If I find a close sub, I will buy a couple to experiment with as they are low cost . I am searching Mouser and Digi-key. 73s Terry

Terry:
Thanks... found it!! What do you think about the wire gauge? Do you think that would be critical? Even with enlarging goggles on, that is a mighty small piece to work with -- That wire is like a human hair width. I wonder why the designer's used such a small gauge in the input circuit if not for it to also serve as fuse to protect the front end.

Terry -- I was wondering why L41 is prone to these problems? What would cause the transformer to one day go bad? Lightening static? Stray RF? As I said in my original post, one day it was receiving great -- next day it was deaf. I leave no antennas connected when I'm not operating the radios.

I think I could get a slightly heavier gauge to make 26 wraps -- though they may need to overlap somewhat. From what I read the wrap technique isn't super critical... but, I do understand your point of maintaining the winding ratio. On the other hand, I may go ahead at look for the #42 gauge enameled wire since I have time waiting on the L4 from Gordon.

Gordon, if you're reading this, please add to my knowledge base concerning the re-wrap of the L41. I'd be interested in anything not covered by K4EAA's website.

Topic: 31583 Message: 31611

Interestingly, I had it on all weekend and on Monday it was rock solid.

I shut it off last night and this morning, I am back to the same problem. Out of frustration, I checked the voltage on the 9v and 3.3v power supplies again. They were both at spec. So then I checked the voltage on the socket jumper on the back and it read 8.83v. So I took it out and put it back in. Now it reads 8.98v and it seems to be solid again.

So I am going the get the schematic out and trace it again to see if I can find a loose connection somewhere.

> Reportedly, according to an article over at Mods.DK, the electrolytic capacitors in the carrier unit can cause this. They recommend replacing them and using a larger cap for the 9V input to the lower carrier board.
>
> On the other hand, the Kenwood TS-820 service bulletin says that noise can be caused by a bad tantalum cap on the PD board in the VCO/PD module. I thought I had noise and so I replaced the tantalum cap with a ceramic bead cap of the same value. And then I found I had the type of instability you describe. I replaced the assembly with a spare and have not investigated why the other module develoepd that problem. But - it appears that the caps on the PD board can cause this too.

Joe-- I agree it doesnt have to be perfect solenoid wound. I dont know why L41 fails like that. Certainly inadvertant transmit RF into the SO-239 jack would do it. Induced lighting? Maybe it is a design weakness? Ken Kempski talks about finding D2 shorted saving the Mosfet and maybe taking out L41? I have seen post where the person said the windings appeared burned black and/or fused together. That almost has to be xmit RF or lighting? What did you see when you took yours apart? If a lead was broken off that sounds like a weakness from day one that just finally gave up? I dont think you did anything based on what you have told us. Terry

Topic: 31519 Message: 31613

Terry: Here's a close-up photo of my L41. The windings appear still bright and shiny. No evidence of burning. But if you look closely on the right side there's a section of wire missing above where it connects to the pin on the right. Later when I touched the upper piece gently with a tweezer, it broke again. Now the upper end is buried in the windings... which was why was having trouble figuring out primary and secondary without unwinding it.

Terry,

Would you, or one of the others in the group, have an old L41 that is basically trash? I would like to obtain one that is not going to be used/rewound to examine. I would like to know more about pin spacings etc. and how the thing is put together in general. I can see the pictures on line but that doesen't do much for me.

Thanks,

Dan KI4AX

31615. Re: TS-830S Low Receive and Little S-meter movement

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-05-31 23:35:48 UTC
From: Terry Wagoner
Topic: 31519 Message: 31615

Joe--From the picture it looks like there are two different guage windings? It looks like a heavy guage over a smaller guage? I have never seen one. Is it possible you may be able to leave one winding in place? Terry

Topic: 31519 Message: 31616

Joe,

I would be curious as to where to get the #42 wire if you are able to locate some.

Dan KI4AX

Dan- I dont have one and hope to never have to wind one! Terry

> Would you, or one of the others in the group, have an old L41 that is basically trash? I would like to obtain one that is not going to be used/rewound to examine. I would like to know more about pin spacings etc. and how the thing is put together in general. I can see the pictures on line but that doesen't do much for me.

From: Joe Loverti
Topic: 31519 Message: 31618

Terry: The photo makes it look as if the gauge differs. In reality it looks like the same gauge. At this point after poking around on the wires, I think I'd rather just start from scratch with fresh wires. After disassembly, it looks like the primary's 6 windings are wound on the bottom section of the spool. And the secondary's 26 windings extent to the top.

Dan:
I found a guy on the antique radio forum who was willing to sell me about 15 ft. of #42 wire. When I get it, I can ask him he'd like to sell more. I don't know how much he has.

Joe- OK understand why you would want to rewind entirely. How will you remove the enamel insulation to make your termination? I have burned it off on larger guage magnet wire. Maybe we could talk Gordon into writing an L41 procedure and post it on his website?
One more thing dont forget to check diode D2 (ohmmeter forward and reverse test) and Q1 if you can. Hate to see you put board back in only to find out Q1 and/or D2 were bad. I dont have much dual gate mosfet experience. I know that you have to be careful with static charge. I suspect you could set Ohmmeter on 10k range and measure from gates to source and drain. If you get a reading I think it would indicate shorted device. Maybe Gordon can advise you on this? Maybe you should replace Q1 as a precaution? I would imagine there are NTE subs that would match specs especially noise figure. Good luck -Terry K9TW

Terry: The photo makes it look as if the gauge differs. In reality it looks like the same gauge. At this point after poking around on the wires, I think I'd rather just start from scratch with fresh wires. After disassembly, it looks like the primary's 6 windings are wound on the bottom section of the spool. And the secondary's 26 windings extent to the top.

Terry: exactly what I'm thinking. I don't want to take it apart again! I'm going to order a new NTE222 (K4EAA) to be on the safe side. but I have no idea what to replace D1 and D2 with? They test OK in circuit, but I'd rather just replace them while I'm inside. Any ideas on substitutes?
